QST,

Operating in a campground using a Hustler on the travel trailer I was doing fine on 75 meters. That is fine until after the rain. Then the auto tuner on the TS-570S could no longer perform. Checked the VSWR and read INFINITY!!.

Worked okay on 20, 10, and 40 MHz.

Finally cut off the plastic weather "seal" to find much water on the coil.

I dried the coil on my T-shirt and everything worked okay.

On the 75-m resonator there was a path for water to enter. Be aware. This resonator to all appearances seemed like new

> I live in a rural area and there is one television station
> that I would like to get but it just barely comes in with
> my current setup (broadband TV antenna with rotor,
> pre-amp, distribution system). <snip>

I did exactly that several years ago. Some coworkers lived outside the city and couldn't watch 'Star Trek' from one of the lower power TV stations in town. I built a half dozen 6-element VHF Channel-8 Yagis based on (scaled from) the NBS design for 2m. I brazed them together out of old conduit and ceiling tile wire and then painted them black. They worked great; noticably better than a wideband commercial antenna. Good enough for the situation that was just out of reach for affordable commercial antennas. Most are still in use today.

One neighbour of one of my coworkers asked him what he was up to. He told the neighbour that he was installing an antenna to get channel 8. The neighbour asked, "Is that legal ?" :-)

If you need a link, then do a Google search on NBS Yagi.
http://www.google.com/search?q=NBS+Yagi

Don't agonize about getting a precise match.

Also, keep in mind the bandwidth (6MHz), especially on the lower channels (VHF 2-6) where it is a significant percentage bandwidth.

Thanks Cam and Dick for the information.. Im going to try making a choke with the coax at the junction to the matching section to see if that impoves things.

What would I need to do differently for this (since I
am dealing with channel 6)? JELo

The NBS paper is quite dated. Good info, but modern computer-designed
antennas are much better.

Take a look a LB's site particularly:

http://www.cebik.com/owa.html

Scaling this to CH6 should be easy.

The main difference is in the receiver which was a superior product in
the ham market for many years, making the 830 a rig of choice for dxers
and contesters. There are some other minor differences, but if you are
considering a 530 or a 830, definitely go with the latter.

I did a quick sketch from the description and it seems you have a
bi-directional Rhombic. No wonder yours signal is so good. Perhaps someone
with a software package could perform an analysis. Very interesting.

Buy more/thicker conduit and wire... :-)

The comment about % bandwidth is that you shouldn't build a very 'highly tuned' antenna. The NBS design is pretty good in this respect.

Makes sense.

One question I have is; from what I have seen, the
reflector and the directors are electrically shorted
together through the boom, but is the driven element
also electrically connected to the boom or is it
supposed to be electrically isolated from the boom
with one half driven by the center conductor and
the other driven by the shield of the feed line coax?
There seems to be different construction methods
that different people use, but yours sounds simple
enough, how did you set up the
driven element? JELo

Especially those who say you don't need no stinkin' radials for verticals.

Amazing what one little missing "a" (eh?) could generate - more interesting
thread that fracabelics :-)
With apology to ra-dials and other insulated dials.

Yuri

BTW I just got 41 dB out of fractaly bent coathanger, just take the coathanger,
straighten it out and bend in like this:

```
* *
* *
* * * *
* *
* * *
```

Can anyone top that? You can use only 13 stars (in the "software") and fit in
the same square envelope, huh?

anand wrote:
"---I am getting good match at the frequencies (that the slots are cut for) but getting an off resonance at 4 GHz."

Is the surface between the slots resonant at 4 GHz?

Chokes may prevent unwanted resonance.

If you don`t excite the antenna at 4 GHz, is this resonance a problem?

Best regards, Richard Harrison, KB5WZI

21. Antenna lies swapping Octoberfest in NY/NJ/PA

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-01 14:51:22 UTC
From: k3bu@aol.com
Message-ID: <20021001105122.05495.00010976@mb-fc.aol.com>
Source record: 133859

Come and have radio-octoberfest fun!
Even if it rains!

You are all invited to (Radio) "Uktoberfest" at Mountainview Resort Verkhovyna (dance hall) in Glen Spey, NY (NY, NJ, PA tri-state area) hosted by the Tesla Radioclub and Ukrainian-American Cultural Foundation - UACF on Saturday, October 5, 2002, starting at 3:00 pm till ???

Come and have fun meeting other hams, DXers, contesters, while having good time and drinking Spaten Oktoberfest and Ukrainian Obolon beer. Enjoy Ukrainian food (special kobassy/wurst, kapusta/sauerkraut, pyrohy/pirogi, sweets) and German food (sauerbraten, spatzel, red cabbage, apple strudel), listen or dance to endless polka's by Czornozem live band and DJ Yurko-Durko. Wear your badge, hat or shirt with callsign proud and meet other radio aficionados around the "radio" table reserved for hams. Free admission to Hams, firemen, police officers, just show your badge.

142 acre Verkhovyna - MountainView Resort is the new home to Tesla Radioclub N2EE station.
Join the semiserious discussion of how many towers do we need to put up there. Come, check it out, join the club and get a free beer. Bring your family and friends.

Directions:
Take Hwy. 84 to Port Jervis, NY exit 1; follow Rt. 6 through Port Jervis to traffic light with Rt. 97/42 signs, go through and follow Rt. 97 west for 10.8 miles to Pond Eddy ("Nolan's" motel on right, bridge on left), turn right onto High Rd. (Rt. 41), go up the steep hill for 1.7 miles, Verkhovyna is on the left.
Plenty of parking.

More info, maps and satellite view of the resort are at www.Verkhovyna.com home page under directions.

See you all there and join us yodeling in Morse code :-)

Nazdorovya, Ein Prosit!

For more info contact
Yuri, K3BU, tel 973 808 1970 Email K3BU@aol.com
pres. Tesla Radioclub, host of Uktoberfest

I've put up a number of antennas made from #14 insulated & stranded
THHN "house wire" which I bought at the local Home Depot for around
$15 for a 500 foot spool of it. Never had a problem with it including
one aerial which had 200 foot horizontal span.

Bill M wrote:
"Maybe struggling for more height is the best answer."

Bill has a good idea. JELo says one of a group of stations barely comes in, despite his rotator. Fresnel may be at work creating alternating parallel strata of high and low intensities of the Channel 6 signal.

There may also be multipath involved at the receiving antenna spot now. There may be sweet and sour spots horizontally sited on his receiving location.

Experiment may disclose the best spot, and height, for a new single-channel antenna.

Greetings,

If you are using coaxial t-line, change to low loss or even open wire parallel t-line.

Other repliers have commented on line loss.

Coaxial line is relatively lossy. I don't know what the frequency of the station you wish to watch is or how long of a t-line run you have.

If it's a UHF station and the line is long your are hurting big time.

Good luck. Read all replies. There's bound to be a good one in here somewhere.

"There seem to be different construction methods that different people use---."

"Plumber`s delight" works for me. A simple TV favorite uses a folded dipole as a driven element.

The center of the folded rod opposite the feedpoint is a zero-potential point and can be welded to the boom. For CH 6 (82 MHz), the folded dipole should be about 62 inches end to end as a 1/2-wave element.

The director should be 5 ft (60 inches) long and spaced 15 inches ahead of the folded dipole.

The reflector should be 6 ft long and spaced 22 inches behind the folded dipole.

Fatter elements broaden the bandwidth slightly.
They affect the resonant lengths slightly.

The drivepoint impedance is a good match for 75-ohm coax. A balun might help. Gain is about 7 dbd. Bandwidth is about 6%, enough for a single channel (82-88 MHz).

This is adapted form Arnold B. Bailey`s "TV and Other Receiving Antennas".

Best regards, Richard Harrison, KB5WZI

It should be connected to the post directly above the "wire" post. Once upon a time I think they used to come with one of those "shorting bar" thingy's you could flick out of the way when not needed. It would have been nice to see the "wire" posts further down and a switch provided for this connection, I have seen a few people modify theirs this way.

What you need to do is to get down to the local
Home Depot and gather a supply of their ready
made poly-vinyl pipe fittings.

They are the light gray ones with pre-threaded
ends for use in domestic low-pressure water lines.
They come in different lengths and diameters.

Cost, pennies per pound, and they make excellent
end insulators.

Gary WG7X.

It seems that they are. I am afraid as far as "free speech" on current US policy goes we are well and truly into "You're either with us or against us" territory. Anyone who dares crticise or in any way question the direction we are going in is instantly branded a terrorist sympathiser, an enemy of free speech, or "anti-American" as I will now be by countless mindless souls for saying so.

I wish they would answer me one thing though, how can someone be an "enemy of free speech" by exercsing their right to it? Converseley how can a government removing the right to free speech be protecting it?

America - "the home of the brave", I don't doubt it, but "the land of the free"? come on, you must be joking.

The boom, directors and reflector are all welded together - the design must take that into account since the dimensions are slightly different if you use an insulated boom.

The driven element is a folded dipole that is insulated from the boom by a slab of plastic (epoxied together). If the driven element were in free space (by itself) then it would be 300 ohms. But installed in the Yagi it is lowered to something much less. I still used a 300-75 ohm balun becaused it made the coax connection easier and it didn't seem to hurt.

Hi Cecil,

This goes by the term "fusing current" for any gauge wire. At #30
that spec is 10.2A for copper. At #14 it climbs to 166A.

This, of course, presumes you either:
a.) observe skin effect, and take that into consideration; or
2.) string pie tins along the length of the wire to negate same.

Alec,

I understand you are concerned about this, but where does it say that the 6MHz of proposed allocation MUST fall within the 70cm ham band?I don't see this in your info. It says " 6 MHz ...within...420-470 MHz'.

If this is a genuine proposal for RE-ALLOCATION I see that your call to action makes sense. However, if it is NOT a proposed RE-ALLOCATION of ham frequencies, then if hams acted as you suggest we will reveal ourselves as unworthy of consideration of this spectrum.

Sincerely, what did I miss in your missive?

Have the people that want the 6MHz chunk ever heard of 'spread spectrum' ?
They could easily design an adaptive, broadband radar waveform for their
(fleet of) satellite(s) that would be virtually immune to interference and
would also have a very low probability of detection. The technologies are
pretty much off-the-shelf. And why limit themselves to 6MHz ? Take the
full 50 MHz (or more) for their spread spectrum signal.

In other words, the required bandwidth could be shared. There is no need
for anyone to move off of the band. All they need is a secondary or
tertiary or etc. asignment for their little project.

BTW, in the depths of the Amazon (for example), I wonder how many users of
70-cm band Ham radio equipment are licensed Amateur Radio Operators ?
People in the less developed countries tend to use cheap Ham equipment (and
frequencies) for all sorts of purposes. Good luck getting them to QRT...

48. Tower to Verticle Ant. Spacing ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-02 02:20:15 UTC
From: Nev <ynotmetwo@bigfoot.com>
Message-ID: <jrlkpu06edlsfg9i77rg3kbarsj8mh4k9k@4ax.com>
Source record: 133736

Is there any "rule of thumb" for the spacing of a verticle antenna side mounted on a tower.

Firstly, I cant use the top of the tower so side mount is my only option.

The "tower" is a 3" (75mm) single pole and the antenna is a commercial VHF 2 x 5/8 colinear for 163 mhz

What is the minimum distance I can side mount the antenna and still obtain "reasonable" omni directional characteristics.

Thanks

Why would Be be cause for caution???? Once alloyed with copper, you will never be able to extract a particle of Be from the metal to become dangerous. You can grind it, sand blast it, machine it, draw it, do anything you want. You will never be able to achieve an airborne particle of berylium.

Berylium Copper alloy is usually used for it's thermal properties. It can be cast to tighter specs and is extremely hard compared to pure copper. It was the material of choice for plastic product molds for many years.

As for antenna wire..... Probably too hard and brittle. A poor choice for mechanical reasons.

Steve

A man I met who has thousands of acres and thousands of pine trees and owned a creosote plant with free 100 foot poles told me about rhombics in practice in the static ridden part of Texas, OK?

Wonderful antennas, they are! Gain, directivity and so on, if either of two directions is on you gotta work it menu! But per this gent there is a hidden gotcha for TRW alley! He claims they are terrible receiving antennas during frontal passages with all the static. Reason; rhombics have numerous high angle spike spurious lobes in their patterns, at least for practical sized thingees we'd normally see for HF ham bands. Per his experience, if he ever got the thunderstorms within not to many miles from him, the additional pickup of thje high angle static generated from all these tronadas makes the antenna a very bad choice while they are around. The high angle lobes and static noise pickup from them significantly destroy the antenna's effectiveness in these situations.

Of it all he noted that despite the magnificent gain on transmit and receive, you still can't work 'em if you can't hear 'em.

Not being affluent enough to try them for 80 and 40 that I like to work, I can't vouch for what he said. But having plotted them on computer I can understand how he just might be right.

Mike - W5WQN in the Bryan-College Station Texas, area ... Not as bad as Florida, but second or close to it, I guess, in the USA.

> can anyone tell me the difference between the two radios? They seem the same
> on the exterior.

As one said, mainly a couple or three extra goodies on the receiver
with the 830. The 530 has IF shift and thats about it as far as
receiver extras, except for the extra filters you can install. The 830
has IF shift, notch, VBT "variable bandwidth tuning", and a tone
control. The 530 is single conversion with an IF at 8.83 mhz. The 830
uses 8.83, but also 455 kc. So with the 830 you can install filters at
either or both IF freqs. I think overall, the VBT is what really sets
the 830 apart from the 530. With the 530, you are stuck at one
bandwidth depending on the mode/filter you are using. If you are on
SSB, you have 2.4 kc filtering , and thats it's unless you install
extra filters. With the 830, you can be at the 2.4 kc bandwidth, and
use the VBT to narrow down to 500 hz with that stock filter. So the
830 is a decent CW rig, even with no extra CW filter.
If you do have the 500 hz CW filter, as I do in my 830, you can narrow
down from appx 500 hz down to about 150 hz or so. Very narrow. So you
can pretty much set the selectivity to whatever you want. Also the 830
has a better speech compressor in it. It's a true RF clipping circuit,
and is one of the best speech compressors out there. Really works
well. You can pump up your average power, and still have good audio
quality. I'm not positive, but I don't think the 530 has a compressor
at all. Both are real good radios, and the transmitters are basically
the same. Both radios have good audio quality, etc. But the 830 has
the extra receiver goodies. It's an old radio, but for just basic
receiver performance, not counting fancy digital bells and whistles,
it can compete with nearly anything out there. I've got an TS-830 and
a VFO-230. The VFO-230 will work with either radio, and is rock stable
from even a cold start. No drift at all with that VFO, and has 5
memories. That VFO makes the 830 feel kind of like a 930.
The internal 830 or 530 vfo's will drift some with temp changes being
an old style L/C vfo. Some people don't notice it much, some do. I'm
fairly anal retentive about stability, so it bugged me have the radio
drift up and down 40 cycles with the A/C cycling off and on. None of
that with the PLL VFO-230.
I recommend it over the VFO-240, which is a dupe of the intermal L/C
vfo.
The 830 is the best of all the old kenwood hybrid tube/solid state
rigs. And it and the 530/530sp's were the last ones made before they
went totally solid state.

So I take it that Anita Roddick was once again practicing what she preaches and the usual suspects took offense. Back in the day, Body Shop bags had a quote on them that said, "The job of a good citizen is to keep his mouth open." Don't recall to whom it was attributed, but it seems Ms Roddick lives it. Good for her.

What's really funny is that someone would think that Ms Roddick's words would offend her patrons, who consist of apolitical women who love the smell of her products (one of the best manufactured smells on the planet) and political women who don't care about makeup and stuff like that but like to support a cheeky woman who tells it like it is. It's kinda like the mentally challenged who think that trashing Steve Earle's song in the press will all of a sudden cause radio stations not to play his stuff. Where do these people come from anyway?

One possibility that comes to mind is that the aluminum is actually coated with a thin coat of Al2O3. In the pure crystaline form, this is known as sapphire. For microabrasives, it would be quite resistant to wear.

I cannot comment on beryllium copper, but there is
another copper alloy that is (was?) widely used by telephone
companies for bare overhead lines. However we used it for
rhombic receiving aerials without any problems (70 foot
wooden poles - three wire rhombic, HF reception on SSB etc.)

I think it might be cadmium copper, but I'm not sure
- I haven't been in that work since 1967 or 8.

regards, Alan.

Try asking the external plant people from your local
telco to see if they can remember it.

Beryllium is carcinogenic. As far as I know the use of Be on rocket nozzles is its most prominent use. One of my colleagues estimates that the public health effect of an exchange of nuclear missiles would be driven more by Be in the atmosphere than by the radiological agents produced.

Does beryllium wire bend well?

Mike, W5WQN wrote:
'Of it all he noted that despite the magnificent gain on transmit and receive, you still can`t work `em if you can`t hear `em."

Magnificent gain and directivity are opposite sides of the same coin. Their values increase and decrease together.

If you could not "hear `em" using a rhombic, most of the world`s commercial receiving stations would be deaf because they use rhombics.

Signal versus noise determines reception. Directivity of the rhombic is by far the best where it is aimed. That`s designed to be the direction of the desired signal. The beamwidth of a practical rhombic may be 15 degrees, the gain may be 15 dbd, and the strongest side-lobe may be 10 db down from the main-lobe.

The main-lobe signal to noise is no worse than for a non-directional antenna. That is, when the signal and noise directions coincide. But, noise from directions outside the main lobe is reduced by a minimum of 10 db.

The rhombic may mistakenly be reputed as a static grabber because it is a broadband antenna. Lightning produces "static" across a wide spectrum. But, it is the job of a receiver to provide frequency selectivity. In commercial stations the receivers are designed with the necessary preselection.

Best regards, Richard Harrison, KB5WZI

Probably a good choice.

The most strength for the smallest wire with sufficient surface conductivity is Copperweld. That`s why commercial and military antennas use it. Stranded Copperweld is popular because the steel inside makes the solid stuff springy and hard to work with.

Best regards, Richard Harrison, KB5WZI

Some hardening would be prefered over pure copper. The hardness and
conductivity would be a factor of the actual alloy created.

The best source of info on both is the manufacturer's site at
http://www.brushwellman.com/www/Technical/DesignGuide/Appendix.html

Note that often when they speek of conductivity they are refering to thermal
conductivity. You have to watch the context in which the term is being
used. At the bottom of the page are links to the tech tables for electrical
conductivity.

My father worked for them for many years before starting his own foundry,
machine shop, and plastics factory. Be is one of the most fascinating
materials I have ever encountered.

I am new to ham radio and have the opportunity to build a 260+ feet horizontal loop around the eaves of the house. One problem I have to deal with is the ladder-line.

I was wondering, what advantages are there between using 600 ohm ladder line Vs. the 450 ohm stuff for use with a low height above ground horizontal loop?

Why use one type or the other for this type of antenna? I will be using an old Johnson Matchbox if that makes any difference.

Thanks

Jack, K9CUN wrote:
"I would l would like to have a bunch of them too."

Compression insulators have the advantage that the wire doesn`t fall when an insulator is crushed.

When voltage rating is low or capacitance is high, multiple insulators are used. Look at the guy attachments to a broadcast tower next chance you get.

Please, please understand the reason for this retoric and for the whole debate. It has nothing to do with Saddam. As Bush's press secretary pointed out, Saddam could be eliminated with a single bullet and anyone familiar with US capability knows that is an extremely viable option which requires no world or even congressional approval.

Republicans do need an issue to divert US voters from our shrinking investments, at least until the November elections. The "You're either with us or against us" retoric can be useful in painting Democrats as traitors to democracy and the American way. Sorry our overseas friends have gotten dragged into it.

Great choice of antenna tuner, it will do you well. If you have trouble matching any particular band, change the feed line length by 1/8 to 1/4 wave on that band, and try again. I use mine for all bands between 80 and 10.

As for feeding the loop.

The 300 ohm line is lighter, and attracts less attention than ladder line. You can mount it using T.V. feed line standoffs. The 100 foot lengths of 22 gauge they sell at RS for $10 has served me well for years.

The impedance at the tuner will be different with equal lengths of 450 or 300, but not necessarily better.

Since you are running this around the house, I take it you will not be trying to feed it a Kilowatt. You will be able to earn the "Worked all electronic devices in my house" award with only 100 watts. If you are running QRP you will have less trouble.

Good Luck
KA9CAR

ynot--- wrote:
"Is there any "rule of thumb" for spacing of a vertical antenna side mounted on a tower?"

The problem is almost the same as a horizontal antenna above the earth. Just look at the horizontal antenna with your head on the ground. There is a difference. The tower face is small.

At 1/2-wave distance from the reflecting surface, all the energy doesn`t make a complete about-face at the reflecting surface, but you do get a null in the direction of the antenna. The reflection is weaker than at closer spacing because less current is induced in the reflector (tower). So, the null is not too severe.

You could do as is usually done and split the energy between multiple radiators located around the tower to get an omni pattern. You can otherwise accept something less than even spacial distribution.

The farther from the tower, the less its influence, but there may be more nulls.

See Fig 12 on page 3-11 of the ARRL Antenna Book (19th edition) for a pattern idea. Substitute tower for ground, and horizontal distance for vertical height.

The antenna catalog should show expected patterns with various mounting schemes.

Best regards, Richard Harrison, KB5WZI

first, it was mentioned in a previous thread that the copper would
reach a point where it becomes brittle when streched beyond a point.
Ice, wind, etc. eventually it breaks. seems that copperweld was the
best for that app. i figure a light rope could be strung tight enough
to be pretty straight and still support a lighter wire which would be
under minimum tension.

second, you don't want to get caught swiping that old copper off the
poles. a lot of the tlelgraph wire is now owned by railroads where
you find it.

Beryllium oxide is used for the insulating material on virtually all
'power grid' tubes such as 8874,8875,8877,4cx300 etc. As far as I know
it is the only material used, but I'm not at all sure about that. There
used to be a caution notice within each new tube box, and there was
information disseminated otherwise cautioning users to never pulverize
beryllium oxide and then breath the resulting dust or powder. Seems it
was fatally toxic rather than carcinogenic in this form, though. It's
been years and I don't remember all the exact specifics.
If you don't crush or pulverize it, it is completely safe to handle
otherwise.

Dick

It's mostly a matter of personal preference. Most hams these day opt
for the 450 ohm line, outside a few purists who just want to use the old
original open wire line.

88. Vertical w/without ground ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-02 20:56:36 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210021256.548f7687@posting.google.com>
Source record: 133775

Hi,

I'm not decided yet, but I would like to buy a R8 vertical to use it for DXing (due to place restriction).
My question is related to the use of ground and radials. I read many posts about this subject but until now none accurately answered to my question yet.

My location is on top of hills where the underground is constituted of rock (blue rocks as they are called, looks like marble but cheaper quality, and virtually impossible to break) with only about 30 cm of soil.

Can we consider such dense rock as a conductive material ? If it is, is it still a better conductor after rain/snow or is it worst (there are some rainy days in ON/LX...) ?

I question because I would like to use a vertical offering the minimum of space near ground level (an R8 placed near ground level requests a space of about 3m dia. if it uses radials 1.2m long). As I will place the vertical 2m high, fixed on the side of a cottage, I would like to restrict its horizontal extension to prevent any injury to people (not mandatory as radials will be probably over 2m high but useful).
If I can benefit of a conductive underground that could maybe help me to select a vertical without radials, if it is of quality and covering a coverage of most bands.

1ï¿½ is this idea of using a rocky underground as "ground" chimeric or realist and
2ï¿½ what vertical (brand, model) could offer this "simplicity" (to not having radials) and should be known as a great DX performer ?
3ï¿½ Otherwise, is there some chances to get a bad SWR (over 8) if I do not install the 6 radials coming with the R8, or has their removing another bad influence I don't know yet and that someone could explain me ?

Thanks for comments.

Not so.

Beryllium oxide (beryllia) is toxic and very expensive to manufacture, so nobody uses it unless it's absolutely essential. The only places it's ever used are where you need its special combination of good insulation and high thermal conductivity. It may be used in a few places *inside* some ceramic-metal tubes, but the ceramic on the outside of those tubes is *not* beryllium oxide.

Think about it: the major part of the heat is released at the anode, and you don't want to let it flow down into the base - so for the main outside ceramic ring you need an ordinary material with a relatively low thermal conductivity. Even if it wasn't toxic and expensive, beryllia would be totally the wrong material here.

Likewise you'll find beryllia in some RF power transistors, as a thermally conducting insulator between the collector (where the heat is released) and the mounting stud or flange. But the main exterior 'pill' is ordinary ceramic.

BTW, it's also a fallacy that pink ceramic means beryllia. It doesn't.

Hi,

I 'm on the way to displace my 40m longwire from 3-5m high to a higher height (0.5 to 1 Lambda, so about 10-15m) to get an optimal response (more lobes) in the HF bands (and then to make a comparison with a future R8).

But,... how to erect a antenna so high ?

I have a house which roof top (chemny)is about 6-7 m high only and on the other side, excepting pintrees 30m high, this is open fields with a few apple trees here and there.

How to place my antenna in height without support ? How did you proceed in a similar environment ? Did you install 2 masts (di.5 cm, 2") 10m heigh each, well anchored in the soil at 3 or 4 points, and 40m apart in your garden ?

Nothing more simple for a "mini" beverage 40m long ?
If I change my mini "beverage" for an inverted V shape (so I only need 1 mast, is there a chance to get a modification in its lobes, sensitivity or directivity (in other words is a inverted V directive in the direction of the opening ?)

Beryllia might also be occasionally used in place of alumina because of its lower dielectric constant (about 6 vs 10 for alumina). I once got to the point of having prototype beryllia hybrid circuit substrates fabricated for a high speed circuit, but the difference wasn't enough to solve the problem at hand so it didn't make it to production.

The most common application for beryllia I've seen is insulators for high power, high voltage (e.g., TV flyback) TO-3 power transistors. The combination of properties Ian mentions, good insulation and high thermal conductivity, are both needed in that situation.

The beryllia substrates I had fabricated, and insulators I've seen, were both white and indistinguishable by eye from alumina.

Hi Chip,

Beryllium copper as wire and sheet stock has been (is) used frequently in antenna design.

As an element, BE is lighter and stronger than AL and is used quite extensively. I believe that there is only one company in the US that refines and sells Be. Handling it as solid is fine. However, as a fine dust or powder, it can be dangerous to some people. About 2% of the population is allergic to it.

As an solid metal, Be is used quite extensively in space borne applications because of its light weight and its strength.

There is a company in MA that is one of the few in the US that actually work with solid Be - mostly machined parts.

I can't comment on the loss properties of Be copper, but don't think its that much of a problem.

Force 12 Sigma-5. True vertical dipole, and a heck of a performer. No ground radials needed. Looks like a capital letter "I"; 9 feet high with the crossbars sticking out 2 feet on each side. I have mine on the roof (flat roof) in a bucket of concrete.

The only problem is that it doesn't cover 30m or 40m, but it is a bit cheaper than the R8. (I use Isotrons for 40 and 80.)

Well, Good, Ian. I always was a bit reluctant to handle it knowing how
dangerous it could be. It's good to know there was no hazard after all.
I assume you've ran all that by the folks at Eimac, they're the people
who included the warning notices.

You would be better off using a Hy-Gain DX-77A. Recommended mounting height is about 8 foot off the ground. No radials needed. Covers 10 through 40 meters including the WARC band. Handles up to 1500 watts. I have one up on my roof and it works great. For more info check it out at:

http://www.hy-gain.com/hy-gain/products.php?prodid=DX-77A

Hope this helps.

The stuff is used in many applications as conductive, non-corroding
springs in electrical devices. High-power rotary selector switch
wipers, etc. The hard-drawn or rolled types in particular would be
pains in the butt to get under control when coiling and uncoiling for
antenna purposes, much worse than Copperweld wire. Fuhgeddit, drive ya

Ekceeequuuuzeeee me!

First, you can prestretch any copper wire, of course you have to be careful not to overstretch or break it. You can feel after initial pull that there is more resistance and that's where you stop. That wire then becomes much stronger than originally, nice and straight, wont "flow" (unless abused).
If you have rope and it gets wet, then when you transmit with normal or decent power you can burn it off and find your antenna on the ground. Been there, done it. You need good insulators especially at the end where is high voltage.

Second, who told you to go swiping wires from telegraph poles? There are occasionaly abandoned wires/ lines with broken wires hanging from the poles. Or you can go and ask to depot, whatever, if they have any or know where is abondoned line. Free for asking and lasts lifetimes.

Live and learn!

Either would be acceptable. For multiband operation, the impedance will vary widely and either one should work and be low loss even at high SWRs.

Thierry, I have no idea what an R8 antenna is. It's just a number. It doesn't matter very much anyway.

But I think you are hopelessly over-complicating and confusing the issue. And you give no idea of what frequency bands you are interested in or whether you intend to transmit or just to receive. Stick to basics. Consider what previous multi-various postings you have read as entertainment value. KISS.

As you are on the top of a hill (an excellent location) with a very poor ground I suggest you don't buy anything. Just erect a vertical or sloper or horizontal dipole, as long as possible, roughly centre-fed with any open-wire or standard 450-ohm feedline, and see how it performs via a tuner at the transceiver end. Bring the feedline away from the antenna at 90 degrees for as long a distance as possible. Avoid a coaxial feedline like the plague!

To lengthen the dipole wire bend its ends at angles of roughly 90 degrees at any convenient different or same directions. Spend your money on the tuner rather than on the antenna. Or make your own tuner to cover your favourite bands.

A simple or dog's-back-leg dipole will perform reasonably well at all frequencies greater than the frequency at which its overall length is about 0.35 or 0.4 wavelengths. Average height above ground or very local obstructions is important. If your antenna length is very restricted there's nothing you can do about it except grin and bear it.

For its overall dimensions this will be the most efficient, multi-band, multi-directional DX antenna system you can expect at your site.

If you are really stuck for space the most efficient antenna is undoubtedly a magloop. It has a built-in tuner. But do not allow me to discourage experiments with dog's-back-legs. Don't throw money at the problem till you've tried everything else. That way both your bank-balance and enjoyable practical experience will be zero. ;o)

The DX will still be waiting eagerly !

****

PS: On the top of a hill, 30 cms of dry, well-drained soil can be expected to be lossy. Any vegetable, fertile matter helps. The underlying rock can be considered to be an insulator. But don't rule out such a situation. Many very short 15 cm buried ground radials of indeterminate length may work satisfactorily at the higher frequencies above 7, 10 or 14 MHz. A shallow-buried wire-mesh mat could be tried and could easily be kept damp

with an occasional bucket of slightly salt water. A short, bottom-loaded
vertical tuned to a single frequency could work well. Soil loss resistance
and radiating efficiency can be accurately determined with a hand-held
antenna impedance analyser at the base of a simple 1/4-wave resonant
vertical antenna. If the measured resonant resistance is less than 50 or 60
ohms then you are laughing.

You failed to read the original post. He referenced Be alloyed with Cu. Berylium Copper. There is no way to create free particles of Berylium from this alloy except possibly with some exotic smelting process to remove the copper.

Even the rocket nozzels that Brush Wellman worked on were an alloy and not pure Berylium.

Thierry, ONL5183 wrote:
"---is an inverted V directive in the direction of the opening?"

Not much. Vertically polarized radiation from the wire slopes fills the wire-end nulls.

There was a short article by William Hanson, WA7OET in the March 1975 issue of "73" magazine on a "40m Inverted Vee Beam" in which he claimed the antenna array was "very satisfying".

An apex-driven Vee is backed with a parasitic Vee reflector. Spacing is 0.15 wl, more or less.

William made the driven element 492/MHz. This seems to be 1/2-wl in freespace for 40m. Feet equal 3.28 x meters if my recollection is correct.

For his reflector he added 5% to the length. Had he added a director, he said he would have subtracted 4%.

He calculated 0.15 wl as 18 ft. I get 19.68 ft, but think this is not critical. William doesn`t seem to give the apex angles, but advises they should be the same in the driven element and reflector ("using two equal length poles"). One tiny problem is the difference in lengths of the vees but they should end some distance above ground, actually, the higher the better. So there`s really no problem. The guys are slightly longer on the driven Vee, as it is shorter than the reflector.

William says: "I heard more DX from there (South America) than I have ever heard on 40 meters before."

William was in the Pacific Northwest State of Washington. I wish he had made some measurements of performance to share, but this was all I found.

If you don`t have good ground coductivity, two poles mght better be used to raise the ends of the dipole. Given good ground, the Vee beam is probably better and as William reported.

In the 1960s, I was working on the NASA ATS-1 Satellite at Hughes Aircraft. We made a cylindrical phased array at VHF using eight coaxial dipoles fabricated from beryllium (they were arrayed around the rocket motor and the thermal and weight characteristics of beryllium made it ideal for this application). Machining Be is a specialized task, as any cuttings or dust must be captured for proper disposal (this was outsourced). We handled the stuff VERY CAREFULLY.

If you have ever seen a photo of a satellite which resembled a squid, that's the one.

Rock is usually considered fairly poor ground. Water might help a
little, but not greatly enough to really consider a big help on those
days.
>

Is there a way to install the antenna high enough that the radials
wouldn't be a bother? The performance of the antenna would be better
also.
>
> 1ï¿½ is this idea of using a rocky underground as "ground" chimeric or
> realist and

I'd consider it fairly lousy as grounds go. But if you use a 1/2 wave
type of antenna "IE: R8, etc, that does not require radials, and mount
it up in the clear , it should do ok.

> 2ï¿½ what vertical (brand, model) could offer this "simplicity" (to not
> having radials) and should be known as a great DX performer ?

I guess great is relative, but any of the 1/2 wave type multiband
verticals should be about equal if they are the same appx height. I
don't know which is better. Never have bought one...

> 3ï¿½ Otherwise, is there some chances to get a bad SWR (over 8) if I do
> not install the 6 radials coming with the R8, or has their removing
> another bad influence I don't know yet and that someone could explain
> me ?

The radials on that antenna are decoupling radials to reduce common mode currents on the feedline. They are not used to reduce ground losses. You could very possibly have funky effects if you delete them. They are not required to have a decent match on a 1/2 wave in general, but they may be included in the overall design of that antenna, and may effect the electrical length a bit. I guess you would just have to try it. But, I don't recommend not using them. I'd try to raise the antenna a little higher on a mast so you can keep them.

Hi Chip,
from an MSDS from ALCO Standard Co. for their product C17510,
Beryllium Copper Alloy 3, "This product presents no health hazards unless it
is welded, burned, ground, or cut." Also, an article cited by the Beryllium
Support Group of the National Jewish Medical Research Center, "MacCordick,
J.M.T. Youinon et al (1995), 'Chronic Beryllium Desease After Exposure to
Low-beryllium-content Copper.'" This last details the medical problems of a
young man who worked with 1.8% beryllium copper wire. Don't let anyone
tell you beryllium shouldn't be treated with respect.

Sounds like gloves and masks to make a solder connection. Very much appreciate
the info Tom; probably more of a hazard just working with the solder itself,
but certainly worth putting in the trivial amount of extra care needed.

I hope you are reading 2m to mean 2 metres, not 2 miles! The tensioning weight is only a 454g sinker (that was a 1lb snapper lead). The sea weather forecast that day was 50 knots (about 90Km per hour). Official weather observations were gusts to 120Km/hour. I have no idea what it actually was around the antenna... but it was pretty strong... however no building damage in the area. The tensioning system is really to let the tree move.

Whilst I say that it will come down one day, that will probably be a bough falling off the tree onto the wire, 'cause I am attached only half way up the tree.

>
> sheave and block. good terms. we never say pulley in CATV. roller. 90

Well, as you know... a block and tackle is used for fibre rope and a purchase is used for wire rope (not just something one does with a credit card!). Rigging has some quaint terms and usage, hasn't it!

>
> it would be nice if you could thread your 2 or 3mm wire inside that

Well, thing I find convenient for creating lash ups for prototyping / temporary work is make a bight near the end of the annealled wire and make a sheet bend through the bight with the rope. Holds quite securely. (No egg insulators or like used of course... well for the middle perhaps but not at the ends.)

>They are not required to have a decent match on a 1/2 wave in general<

They are an integral part of the OCFD radiator and removing them is akin to removing a major portion of the antenna.

>but they may be included in the overall design of that antenna<

Must be included!

>...and may effect the electrical length a bit.<

An understatement. BTW, for a ground independent (or elevated feed) vertical, there's no penalty at all--and likely some advantage--to putting the radials on top where nobody can become tangled up in them. Better yet, flip the whole thing on its side and pick up 5 dB or so in performance (one of those nasty little secrets all-band vertical manufacturers don't advertise).

Hi Thierry,

Stick with your G5RV or the wire antennas to the distant trees. If you want to experiment with verticals, buy aluminum tubing of the same height and drive it directly (through a tuner or through a match at the antenna end). As you have literally few options in regard to ground, then it shouldn't take long to try them all (an afternoon?).

No multi-band antenna is going to offer any better characteristics than what you have already, or could put up simply, and cheaply. The only benefit of these multi-band antennas is that you don't need to tune - maybe. Worse yet, is that any actual beneficial difference between the multi-band and the simple design is not perceptible (and hardly qualifies as beneficial, but you can use that as bragging rights to justify the cost).

Only with respect to how much digging you're able to do before
keeling over. :-)

> I'd rather bury them about 1 or 2 inches.

Seriously, unless you're talking in terms lots of feet, it makes
no difference.

Through exhaustive research I've found the optimum depth to be that
of the slit cut by my neighbor's gas powered edge trimmer. Hint, hint.

Drill them out with the correct size drill per the instructions. The drill size is the same diameter as the original holes. Make sure you keep the drill centered.
There is a "portable drill press attachment" available from hardware outlets, like Sears, that will help you stay centered on the element and stabilize the process.

>Anyone know what the optimum antenna length for FM radio is?

John, The length that receives the best signals, if you are trying to receive, and the length that transmits the best signal if you are trying to transmit. If both, another length may work better.
Your question is rather broad, it would help if we knew exactly what you are trying to do. This is an amateur radio newsgroup, so do you wish to construct an antenna for 2m FM? If you are trying to receive commercial FM broadcast signals that is another matter. I would be glad to help in any case, if I can.

Fred, A virtical? Wasn't that some kind of diet drink that was popular in the late 60s, or was that virtrecal?? I have had good results with a 5' folded dipole made from 300 ohm twin lead on the FM broadcast band.

10.5"!!!! no wonder it won't work! I'd try and build a better one. Your wavelingth at 88.5MHz is: 3.3898 meters, so a good choice would be 5.288ft. Useing: Length ft = 468/f MHz. This will yeld a 1/2 wavelingth ant. I like the 1/2 over the 1/4 because it dosen't require a ground plane, however it is much longer. At 100mw you will need as much gain you can get in order to get the coverage you need. I beleave Radio Shack sells a 72" telescopic whip. You could try and replace it and that way if you want to raise your freq. you can shorten the new whip to the desired length. Also, Ramsey Electronics sells a 1watt broad band amp, however, you'll need to replace the whip ant with an RCA female type jack and a RCA male to RCA male coax patch cable. For some really weird reason, Ramsey and TenTec use RCA jacks instead of BNC or some other widely accepted RF connectors... Whether or not you use the amp, i'd still ditch the ripoff of an antenna that came with it.
By the way, it's never too late to earn you Ham ticket!
I'm into low power, (qrp, less then 5w), bicycle moble on HF and satelite work on the VHF/UHF bands. For this kind of stuff antenna is key!!!
I find that there is something for people of all walks of life in ham radio, all ages too...

Thanks for all your suggestions.
FYI my current longwire installation in ON is visible here :
http://www.astrosurf.com/lombry/qsl-longwire.htm
I have also an active magnetic loop in LX but the result as poor due
to a lot of QRM (see also a review of ALA-330 on my site).

I wrote a long answer answering to all your suggestions but I lost
it.. :-((
So I rewrite only the conclusion, a bit longer that the previous one :

According many OM, the wires ((I mean multiband dipole/longwire, G5RV,
etc) have often your preference... and partially for financial
reasons, but not only for this.
For me, theoretically (which is far from the experience in the field)
both vertical and wires seems to be on par. I only suspect wires to be
better performers when they are erected near 1 lamba above the ground
(so at about 14m for the 20m band) where they display much more low
angle lobes, useful for DXing. See test at various height on
http://www.astrosurf.com/lombry/antenna.htm (mid page)

So could you conclude like me the following sentences : if I can erect
a wire antenna far enough above ground, e.g. a 40m G5RV, it will
perform better than any vertical, 10 times more expensive. I coiuld
even fold it if I move to an appartment with limited space.
But if I cannot place my wire so high (and thus if I am limited to
ground level, about 2-3m high for the highest point accessible), it
should be more useful to erect a vertical (or bent it a lot as
suggested a reader to get gain !)... Is this realist ?

At last, the most difficult case, the intermediate one : if I can
acces my chemny (top of roof at about 6m high), what could be the best
solution : to tie a 100' G5RV or to erect from this height a vertical
? Personnally I suspect the vertical to be here also "better" for
DXing as the heigh is not enough yet for the wires (0.5 lambda is a
minimum and 6m is not 7m yet, even if I know that many OM use wires at

such height successfuly, but I am searching for the optimized solution).

Of course if you can give me an appreciation based on your own experience, if you tested wires and vertical at various height, and have made comparisons, that could help ;-)

Thanks for your advices.

Thierry

A G5RV jr. is assumed to be a half-sized G5RV. As such, it is 1.5WL
on 10m fed with 1/2WL of twinlead. It should be resonant somewhere
on 10m and have a nice cloverleaf pattern. Why do you think it has
lousy performance on 10m?

For a dipole, about 468/98 ~ 4.8 ft. Or cut it for your favorite
frequency.

You forgot the last part of that sentence - ham radio is a hobby that serves a public service. And it is that public service that sets ham radio apart from the other hobby or recreational radio users (CB, GMRS, FRS, or whatever).

And please don't now claim that hams don't do public service, because I know for a fact that large numbers do. In fact, based on my experience, the only hams making these claims are the hams not doing public service themselves (perhaps to justify their own inactivity).

> It can not justify the frequencies it has.

Ham operators don't have to "justify" the frequencies allocated to them. We don't allocate frequencies to ourselves - government agencies do. And it is those agencies that have to justify their decisions to allocate frequencies. And judging from the number of bands and frequencies available to us, they have not had a problem justifying their decisions so far.

> 70 cm should be reallocated to commercial use
> since hams do not deserve it.

A bold statement, Barry, especially when absolutely nothing is offered to back it up. Why don't you explain why we don't "deserve" it? Are you going to claim nobody is using those frequencies? If so, I suggest you listen a little more closely. True, the the band is not being used as much as it could, but the same could have been said about the 6m band a few years ago (a band growing more popular each day).

> They may as well have them since hams do not
> need them.

You consistently refer to hams in the third person. Are you even an ham operator? If not, why is this of interest to you? If you are a ham, why do you have such a negative opinion of your fellow ham operators - and such a destructive attitude towards this radio service? Instead of advocating the removal of our frequencies, why don't you do something more constructive - like actually using the frequencies?

Belrose has written about the problems of using an extended length
dipole in an "inverted-vee" configuration.

See: "On Center-Fed Multiband Dipoles", QST, March 1994, pp 34-36.

The "nice cloverleaf pattern" occurs with a horizontal dipole. The
inverted-vee "G5RV" moves the high current regions away from center
and then places them closer to ground. You're better off with a
half-wave dipole.

sheet bend. that must be the one i forgot the name of. for joining
disimilar ropes. similar to a square knot but the end of the
rope/wire doesn't pass back through the bight but just weaves under
it's own input to the bight.

Maybe someone can use some of these as loading coils
or in a homebrew tuner:

FOR SALE:

Two James Millen adjustable coils on ceramic forms.
Type 69045 Dimensions 2-1/8" long X 1/2" diameter.
Single hole mounting, solder terminals.
QTY 2 available for $4.00 each
http://home.cfl.rr.com/happysurfer/imag/two_james.jpg

3 turn link with two tube plate caps attached.
Ideal for homebrewing.
Bakelite swinging arm for coupler. Pivot goes to ceramic "BVL" Jack
bar
with 4
metal jack sockets, and pivot brackets that are wired to two large
plate
caps made
for tubes with 1/2" diameter plate cap. Part of a BVL tank system.
Has enameled copper wire and some very useful hardware attached.
Link coil dimensions 2-1/2" diameter. Enamelled 18 gauge copper wire.
QTY 1 only at $5.00
http://home.cfl.rr.com/happysurfer/imag/3turn_link.jpg

6 turn air wound coil - airdux style. Dimensions 3/4" long X
2" diameter. Inductance 2.2 uH.
One only - available for $3.00
http://home.cfl.rr.com/happysurfer/imag/6turn_air_wound_coil.jpg

18 turn coil. Airdux style. 1.75" long and 2" diameter. 10 TPI.
12.2 uH. Will sell for $5.00
Similar to above coil only longer. Picture available.

30 turn air core coil. Dimensions are 4" long and 2" in diameter.
Inductance is 18 uH. QTY 1 only at $6.00
http://home.cfl.rr.com/happysurfer/imag/30turn_air_core.jpg

48 turn air core coil - airdux style. Has Dimensions 7" long X 2"
diameter.
Inductance is 29 uH. QTY 1 only available for $10.00
http://home.cfl.rr.com/happysurfer/imag/48_turn_air_core.jpg

91 turn air core coil - Measures 6.5" in length and 1.5" diameter. 14
turns per inch.
65 uH inductance. Excellent with plexiglas support and four mounting
holes. QTY 1 only for $12.00

http://home.cfl.rr.com/happysurfer/imag/91turn_air_core_coil.jpg

Ceramic coil, split off-center. Has total of 20 turns with a
tap at 13 turns.
On white ceramic form - former dimensions 3" long X 1.5" diameter.
Coil length is 2". Inductance is 8.56 uH.
Qty 1 only for $3.00
http://home.cfl.rr.com/happysurfer/imag/ceramic_coil_split.jpg

Ceramic coil with approx 110 turns of green cotton covered wire.
White ceramic form has dimensions - 2" long X 1.5" diameter.
Inductance is around 330 uH. Suitable for AM band or LF applications.
Has screw terminals and solder lugs for connection.
New old stock. QTY 1 only for $4.00
http://home.cfl.rr.com/happysurfer/imag/ceramic_coil_with.jpg

Coil form, ribbed white ceramic. Dimensions are 5" long and
2" diameter.
Ribbed style with slots for wire. Designed to hold 26 turns and
would have about 20 uH. Has 4 mounting holes on each end.
Has been repaired; looks fine, hence low price.
Qty 1 only at $1.00
http://home.cfl.rr.com/happysurfer/imag/coil_form_ribbed.jpg

Coil form - odd design ribbed ceramic former with 6 terminals on
base and three nice threaded holes for mounting screws.
Dimensions are 2-1/2" tall X 1-1/8" diameter.
Inner coupling coil is 7/8" diameter with tapped coil of enamelled
wire brought out to three terminals.
Qty 1 available for $3.00
http://home.cfl.rr.com/happysurfer/imag/coil_form_odd.jpg

Multi-tapped coil. Unique design attached to a PC board with a tap
for every turn.
Airdux type air core form. Coil has a total of 32 turns and dimensions
of
4" long X
1.5" diameter. Approx 12.5 uH.
QTY 1 available for $6.00
http://home.cfl.rr.com/happysurfer/imag/Multi-tapped_coil.jpg

14 MHz plug-in tank coil with link coupling. 20m coil on 5-pin base.
Marked as model 2420. Medium size. Airdux style coil has 11 turns
and the link outside it has 3 turns. QTY 1 only for $5.00
http://home.cfl.rr.com/happysurfer/imag/plug_in_coil_with_link.jpg

More soon.

Sorry, I missed the "inverted-vee" part. For good performance on the
higher bands, a G5RV should NOT be used in an inverted-V configuration.

Before you even consider a rhombic antenna, get out a compass and a tape measure. This is a big mother of an antenna. I was bragging to my radio buddies about having a big erection, A rhombic, and guess what, NOT ENOUGH SPACE. I have heard them on 20 M from ZS, VK and ZL and they sound fabulous. I have a 50 acre farm in the Canadian bush so if you are real estate challenged, forget it!!!!

Earthling wrote:
"What type of antenna---?"

A longer antenna for your FM sender is likely illegal.

Free-space wavelength is 300 / MHz.

300 / 88.5 = 3.39 meters or 11.12 ft.

A 1/2-wave antenna for 88.5 MHz would be about half of of 11.2 ft, or about 5.56 ft. It is shortened by "end effect" to about 95% or 5.28 feet.

It`s better too long than too short for most antennas because the radiation resistance change is slower above first resonant length than below the length of first resonance. Above first resonance length, the radiation resistance oscllates around the free-space first resonance radiation resistance value.

As already noted, Radio Shack sells a cheap ready-made 300-ohm folded dipole with some 300-ohm twinlead attached. That is hard to beat. The dipole can be placed for vertical or horizontal polarization or anything in-between. The exact length of antenna or leadin is unimportant.

A legal wireless system may be made completely from 300-ohm twinlead connected to the sender output. Run the twinlead through every room and outdoors listening point. At the far end of the twinlead run terminate the twinlead with a 330-ohm resistor. Two-way radio uses this method for communications in tunnels etc.

Earthling won`t need to modify anything inside his sender to attach twinlead using crocodile/gator clips to his telescoping antenna and its chassis.

Contactless coupling to a vertical whip is possible using a toroid core suitable for 88 Mhz in this case. The core encircles the base of the radiator. It works just like a clamp-on ammeter. A one-turn coil is made by the antenna circuit. Additional turns are wound onto the core to match the 300-ohm feedline. Grounded radio towers have been driven from transmitters using toroids around the tower. This is costly, so it doesnt find much commercial use.

Best regards, Richard Harrison, KB5WZI

Mine is 272' feet and works fine on all bands from 80 up to 10.
For 160, I have to short the ends of the antenna feed line together
at the shack, and feed it as a random wire. I use a manual tuner
on 10 and 15 & 160; the 746 autotuner works on the other bands.
I believe - but do not know - that you can adjust the length
of the ladder line such that a good autotuner would handle
80 through 10. Don't know what the autotuner would do with
the thing fed as a random on 160.

172. Program TOPHAT2

Newsgroup: rec.radio.amateur.antenna

Message-ID: <ankh0s$t5h$1@venus.btinternet.com>
Source record: 133711

Program TOPHAT2.exe is an improved version of TopHat1.

Part of introductory notes -

"PERFORMANCE OF SHORT, VERTICAL, TOP-CAPACITANCE-LOADED ANTENNAS

Capacitance loading of a short vertical antenna can improve radiating efficiency better than inductance loading. Best possible improvement for a 2/3-height loading coil relative to base loading is typically 3 dB. But a large top hat can improve performance by more than 6 dB. In this program the hat is a number of horizontal radial wires or rods optionally surrounded by a wire circle.

Top-capacitance loading improves radiating efficiency in two ways -

(1) A more uniform distribution of antenna current versus height results in an increase in radiation resistance for no loss in the top-hat. Whereas the high loss resistance of a raised coil can outweigh the benefit of increased radiation resistance.

(2) A tuning coil is always necessary. But its inductance is less when a capacitance hat is fitted and if overall coil dimensions are unchanged then loss in the coil is much smaller. A more uniform current due to a top hat lessens the advantage of fitting the coil part-way up the antenna. The coil can then be combined with the Z-match network located between antenna and the transmitter as in this program."

Download in a few seconds program TOPHAT2 from website below. Run immediately.

Nonsense, asking questions is nothing to feel ashamed of. If that were true,
I'd be inducted into the 'Hall of Shame.' <ggg> I believe the correct answer
(Please correct me if I err, group.) is that the 450 Ohms & 600 Ohms are
measurements of impedance rather tthan resistance. It's important to match
the impedance to allow the full transfer of energy wrt an antenna system.
Hope that helped some. Take care now. :-)

The main problem in the above application is the ability of the capacitor to handle the RF current. True transmitting caps are rated in RF amps at a specific frequency. Air and vacuum caps are the least trouble because they can handle large RF currents without heating.

Lessee, if you want -j80 ohms at 1.9 MHz, you'll need - umm - 1,047 pF. A triple-gang BC variable is just enough.

Sure, the Berylium Copper alloy can be cast to very exact tolerances and is very stiff. It will not deform from the forces of chewing a steak or biting the dog... what have you.

Berylium particles have only been problematic when inhaled into the lungs. No particles can be extracted from the alloy in normal day to day use/wear and tear. That is why it is in every home practically in several applications and not causing any problems.

Steve

178. Re: 600 or 450 ohm Ladder Line?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-04 17:41:14 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <uprklrouossl91@corp.supernews.com>
Source record: 133717

Although the units of the line's impedance are ohms, it doesn't represent resistance. For a completely lossless line, the characteristic impedance is the square root of the ratio of inductance per unit length to capacitance per unit length, which has the units ohms. It's also the ratio of voltage to current anywhere along a line that's terminated with its characteristic impedance. This ratio also has ohms as its unit, just like the ratio of voltage to current in a circuit. But it doesn't represent loss resistance -- a completely lossless line has a characteristic impedance that's very nearly the same as a pretty lossy line.

At UHF and below, the primary source of loss in dry, decent quality transmission line is conductor resistance. Because the current flows in a very shallow layer along the surface(*) of the wire at radio frequencies, the resistance is a lot higher than it would be for DC. The layer gets shallower as the frequency increases, resulting in increasing loss at higher frequencies. The loss in any length of line, in watts, is I^2*R, where R is the RF resistance per unit length of the conductors. For a given power, the current is less on a high impedance line, resulting in lower loss.

The presence of a typical amount loss doesn't change a transmission line's impedance much, so the small change is usually ignored.

You'll find a lot more about transmission lines in the ARRL Antenna Book or ARRL Handbook.

Roy Lewallen, W7EL

(*) The current density actually decreases exponentially inward from the surface, and drops to a very low value within a small distance. The distance from the surface where it reaches about 37% (1/e) of the surface value is called the skin depth.

I've been going through my collection of old CQ Magazines, yah know when Wayne was there. I ran across a curious type of a dipole called a conical. The author claimed to increase bandwidth as well as radiation resistance close to the ground by parrelleling two folded dipoles Maypole fashion with each dipole leg 90 deg to the other. He claimed an improvement of at least an S unit above a dipole at the same height (28 feet) as well as increased bandwidth due to the staggered resonances of the two dipoles i.e. one tuned to the high and the other to the low end of the band. Does it sound reasonable that this antenna should have any greater efficiency than an ordinary dipole?

>Hope that helped some. Take care now. :-)

Hi Bert,

The 450 or 600 Ohm specification being for Impedance fails to reveal
that none of that Impedance is reactance - the more important
consideration. That same 450 or 600 Ohms is in relation to the
intended load (even if seen through a transformer to some other value)
which must be entirely resistive (and thus maintaining a match without
reactance).

Another perspective is to consider the Hi Tension lines crossing the
country. They run at elevated potentials (the reason to use
300/450/600 Ohm lines) to reduce current demand for the same power
delivered. Thus the same copper loses less power in passing the low
current high voltage to a distant load.

Now, as it is a rare occasion when that load is actually that high in
Impedance (usually found in very, very, large antennas like a
rhombic), the application of these transmission lines often finds them
terminated in much lower load Impedances. In this regard, the SWR is
usually astronomical (and this is anticipated, not just a whim of
design); but the high-Z of the line copes by the same methodology (low
current high volts) which results in lower loss for the inescapable
mismatch supported on the line before it hits your tuner.

I want to thank everyone that responded to my inquiry.

I had thought that perhaps the Johnson Matchbox was
originally designed for use with 600ohm ladder-line hence
my inquiry.

I will go with 450 line since it will be easier to route.
Getting it wet is not an issue as it will be run through the
attic and not exposed to the elements.

I had heard that the Matchbox could be modified for use
on 160m, anyone know how or have a link?

Also heard the Matchbox could tune the WARC bands
by simply switching to the nearest band-switch position, true?
Since I don't have an antenna as of yet I havn't been able to try it myself.

Indeed, the WAA award comment was funny.

Thanks again.

There are two line characteristics which matter most. Characteristic impedance Zo and wire resistance R.

A high Zo line alows the SAME power to flow along the line at a HIGHER voltage and at a lower current.

Watts = Amps times Volts.

If it flows at a lower current for the same wire resistance then it suffers less loss.

****

If a 600-ohm line and a 50-ohm line both have the same wire resistance, then the 50-ohm line will have X times more loss (in decibels) than the 600-ohm line.

****

Attenuation of any sort of line is 4.34 * R / Zo decibels per 100 feet,

where R is the HF wire resistance per 100 feet.

****

X = 3.46

(Come on now, own up - how many of you thought the loss would be 12 times higher?)

Hi Steve,

They used to say the mercury in dental work was OK too because of the amalgam, "no problems" - science and dentistry now tends away from amalgam because of the mercury leaching out. My dentist's work has been mercury free for at least 15 years. It is never an issue of any particular single exposure, rather the problem is in constant "low level" exposure. Such toxins are cumulative.

Hi Tony,

This is the problem of one-shot testimonials, they never really answer
anything, but the testifier will thump the bible twice as hard to make
up for it.

More than likely, the added element filled in a coverage gap and that
gain has been applied to the entire design inappropriately.

I have one, and I could NEVER get it to resonate anywhere in the 6
meter band. It may be just be a bad one, because I have 6 other
Hamsticks, and they all work FB. I bought mine from Iron Horse.
Maybe another brand of Hamstick might be a better choice for 6
meters. Or maybe I just got a lemon.

>
> - Mike KB3EIA -

The problem with a trombone capacitor is that you can not easily
adjust it. In a magnetic loop antenna, the bandwidth at resonance is
very narrow, maybe just a few Khz, This means you have to re-adjust
the capacitor every time you QSY even a tad..unless you want to park
on one frequency. A better solution is a vacuum variable capacitor.
You can remotely tune it from your shack using a cordless screwdriver
motor. I built one, so I know.
I spent a ton of money learning about and building magnetic loops.
Almost got divorced over it too! In the end, I discovered it was the
biggest folly of my 38 years in Ham Radio. You will get better
performance from a hunk of wire tossed in a tree. Good luck!

The quick and dirty answer is that higher impedance = higher efficiency
than low impedance line due to lower loss incurred since the current
flow is lower.
Do the Ohm's law math. Low resistance = higher current for a given
power level which = more I^2R loss which = lower efficiency. That = less
RF energy arriving at the antenna.

This is true with any electrical circuit, not just antenna feedlines.

I've a purely technical question.

I've built dipoles using a 1/4 wave line from the feed center down 1/4 wave and soldered to the coax braid. Good isolation.

Can I do the same using just a single wire (16 ga solid)? Did not check this aspect out when I had the eqmt to do so...

Does that mean that 31.623 mA through a 1kilohm resistor will produce more
power dissipation than 1mA through a 1Megohm resistor?

Of course it's different from inverted-V dipoles that have the maximum
current at the feedpoints. A multi-wavelength inverted-V is absolutely
terrible and only an S-unit better than an expensive vertical.

At HF, the transmission line losses are mostly due to copper I^2*R losses.
The current in the transmission line is inversely proportional to the
characteristic impedance, i.e. higher Z0 = lower I^2*R losses.

Hi there,

I am about to put my first directional HF antenna up.
(An OB6-3M tri-band with 20m Moxon from www.optibeam.de)
However, as directional HF antennas are new to me, I am wondering in what direction I should leave the "dead angel" of my antenna rotor.

For your information, I am living in Belgium (ON). My guess would be North because few day-time 10-20m QSOs would be in that direction.
Is this good reasoning?
Please correct me if I am wrong.

Tnx & 73 de

Dick Carroll wrote - Do the Ohm's law math.

==========

Dick, that's the trouble with education these days !

The kids are taught from the age of 5 that 'maths' is frightening hard work.

Primary school teachers are in short supply and want paying extra for teaching 'maths.'

They get kicks out of being called 'maths' teachers. It's a subtle form of promotion. It sounds more distinguished.

Ill-educated Education Authorities themselves advertise for school teachers with the ability to teach 'maths' to juniors.

The dread of 'maths' and 'advanced maths' propagates all the way to the colleges and universities.

Authors of articles in radio magazines, annuals and compendiums feel they must appologise at the outset for including such mind boggling mathematical phrases as V=I*R.

Technical editors skip whole paragraphs. The printers are no better.

It results in employers having to teach ARITHMETIC to new employees before they can be expected to be of any use.

Beaming Government Ministers of Education visit classrooms and enquire from toddlers how they are doing at 'maths'.

Aged distinguished professors of engineering and science are obliged to teach ARITHMETIC to 1st year, 20-year old students before they can make any sense out of a quadratic equation. Logs come in year 2.

Some years back, just before a General Election, a prospective member of parliament canvassing voters in a bar was asked what seven nines were. He didn't know.

A few days later he lost his cash deposit. Otherwise he might have ended up in number 11 Downing Street as the Chancellor of the Exchequer !

But ragged South American street urchins, never had a school, living with rats in city sewers, pushing home-rolled cannabis cigarettes, can work out the change for 5 ten peseto notes for 7.75 fags at 5.5 pesitos each in milliseconds.

The last I heard was about a team of mathematical research workers visiting Rio to discover how it was done.

And Tony says "Education, Education, Education" before getting on with more important matters like oil.

Reg.

>but why is it a 450 or 600 ohm
>transmission line 'conveys' energy better and more efficiently than a line
>with less resistance?

I always thought it was because the "lower" impedance transmission lines were coaxial cable. Coax has higher dielectric loss, as well as I^2*R losses. Open wire line generally uses larger conductors than coax. On coaxial lines having a high VSWR, the return loss is high, because of dielectric losses, so less power is radiated. 450 or 600 ohm line does not have these losses, so more power is radiated. These lines can operate with a high VSWR, and still deliver most of your power to your antenna, where it will be radiated.
Air dielectric coaxial cable with a 600 ohm characteristic impedance will work as well as open wire line, but producing it for the average ham to use is impossible because of the physics of transmission lines.
But, you get the idea, 50 ohm coax is a lot more lossy than 600 ohm open wire line at high SWR.

Nope, that's wrong. The reason coax is lossier than open wire line isn't because of the dielectric. In a coax cable, the field from the center conductor all couples to the outer conductor, with a relatively short path between. It's this very tight coupling (think of it as high capacitance if you like) that leads to the lower impedances for coax than you see with open wire line. The only reason that foam dielectric or partial air dielectric coax cable has lower loss than solid dielctric coax is that for a given Z0 and outer diameter, the center conductor is larger. This of course reduces the conductor loss.

What I've said is verifiable in a number of ways. One is to calculate the dielectric and conductor loss from published material properties. You'll see that the dielectric loss is so much less than the conductor loss as to be insignificant until you reach somewhere around 1 - 10 GHz. Above that, the dielectric loss does dominate. If you have a curve of measured cable loss, you can see where this happens by the change in slope -- in the conductor loss region, the loss in dB increases as the square root of frequency. In the dielectric loss region, it increases in direct proportion to frequency. That is, in fact, how the dielectric loss eventually "catches up" with the conductor loss -- it's a stronger function of frequency.

I assume that the dielectric loss begins dominating at a lower frequency for open wire line than it does for coax, but I don't have any supporting data. Any curves I've seen of open wire or ladder line over the HF-VHF range at least show the expected square root dependency of loss on frequency, so over that range at least the conductor loss still dominates.

Serge,

You usually don't have a chioce, or maybe a choice of two. The stops are usually at SOUTH, so you can have NORTH in the center. Some rotors let you reverse the scale so you can have SOUTH in the center. The reasoning is, when you turn your antenna from EAST to WEST, do you want to go past NORTH or past SOUTH?. There is no dead spot as such. They will turn 360 degrees, or almost. Yaesu rotators will turn 540 degrees. From Belgium, unless you are switching between S. America and the Middle East a lot, you will want North center - which means stop at SOUTH, center on NORTH. If you put the stop at NORTH, you would have to go almost full circle to swing from the UK to say Sweden.

There's no magic frequency where skin effect begins to occur. It's present at any frequency, just not at D.C. But the skin depth decreases in proportion to the square root of the frequency, so it becomes shallower as the frequency increases. Depending on the wire size and conductivity, somewhere well below the RF range the skin depth becomes comparable to the wire diameter. And somewhere around there, and at lower frequencies, the resistance is essentially the same as the DC resistance of the wire. By the time you get to RF, though, all but the very tiniest wires are several skin depths in diameter, so the current decays to a negligible value well before it reaches the center of the wire.

Forgetting definitions (I realize you want to know what time it is, and not the history of clocks) do the following:

Get a piece of flat television twinlead, also called 300 ohm twinlead or ribbon.

1. Cut it 5 foot long
1A. then remove the insulation from both wires on one end and the twist the wires together.

1B. Do the same thing at the other end.

You now have a piece of wire that looks like this:

```
_____________________________________ Top Wire
X X
X_____________________________________X Bottom
```

where the X = the twisted wires on the end.

2. go to the middle of the bottom wire and cut ONLY the bottom wire in two and remove the insulation from each side of the cut. Connect another piece of twinlead to the two pieces you just exposed.

you now have:

```
_____________________________________
X X
X_______________ _______________X
| |
```

Make the twinlead of sufficient length to go from your new "folded dipole" to your radio.

Put a thumb tack through each end and stick it to a wall.

Your done!

Improvement #1 Solder all connections.

Improvement #2 align the direction of the antenna , do this by holding your arms out and facing in the direction of the radio station. Now pretend you are holding your dipole in your arms. Mount the dipole so it faces the station exactly as it would held in your arms.

Hope that helps!

|coaxial cable.

No.

|Coax has higher dielectric loss, as well as I^2*R losses.

Technically true, but practically the dielectric loss at HF to VHF is
a non-issue.

| Open
|wire line generally uses larger conductors than coax.

Maybe, maybe not. Six-inch spaced 600 ohm open wire will use 12 AWG
(0.08"). The center conductor of RG213 is the same size and the outer
conductor is a hell of a lot bigger than that. I have some "450 ohm"
window line with 18 AWG conductors

|On coaxial lines having
|a high VSWR, the return loss is high, because of dielectric losses, so less
|power is radiated.

Once again you are overestimating the effects of dielectric loss. The
reason loss is higher in lines using dielectric is that the presence
of the dielectric requires smaller conductors be used if a constant Zo
is to be maintained. It is the reduction of conductor size, hence
higher I^2 R loss, that causes the increased loss, not the presence of
the dielectric.

|450 or 600 ohm line does not have these losses, so more
|power is radiated. These lines can operate with a high VSWR, and still
|deliver most of your power to your antenna, where it will be radiated.

Unless of course, you are using window line and you add water <g>.

212. G5RV, single or double length ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-05 02:02:36 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210041802.2a8d@posting.google.com>
Source record: 133651

Hi,

After have discussed and questioning many readers of this forum these last weeks about the buying of a vertical vs a dipole for DXing and mainly listening purposes (and very soon to TX I hope), from your comments and the ones of a french forum I am happy to tell you I decided to buy... a G5RV, at last !,
and FYI from http://www.antennasmore.com/g5rv.htm , as it seems to display the best quality and e elelnts reviews on eham website.

This is not a very original announcement but at least I could now do some comparisons between performances of this dipole, my ALA-330 mag loop and my 40m longwire.

There is however one last question : must I buy a full length G5RV (102', 31m) or a double size (204' 67m) if I'm first interested in DXing in bands from 20m to 10m (mainly in the summer time but of course in the lower ones too, 80-40m to 10m, in the winter).

200' is rather long, even if I can fold it a bit in inverted V if I attach it to a pintree or to mast I could install on my roof top (chemny). But don't you think that length could be intersted to get more low angles and narrower lobes ?

Theoretically what are really the benefits of using such a long dipole vs the 100' version ?,
And practically is there really a difference (a boom of the S-meter ?, lower noise, probably not...) with the 100' v ?
At last is there a benefit of using the 200' if one day I have to fold it or to give it a shape in zig-zag (shape of W as seen from above) if there is a lack of place ?

Thanks for your comments

The simple answer is... the 102 foot one is good for 80-10. The longer version is normally purchased so one can also work 160 meters. Don't know if the extra length will help on the higher bands that seem to be of interst to you.

Nice rant, Reg, but all too accurate, I'm afraid...my YF spent her
working career as a 5th grade schoolteacher. Long ago she mentioned,
much to my surprise, that they no longer taught students to memorize the
multiplication table. The Education Establishment had decided that such
rote memorization wasn't proper. It also always surprised me how many
students arrived at 5th grade level who couldn't read. They usually
could after she got finished with them, though.

216. A portable antenna for DXing ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-05 02:30:30 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210041830.5f8061fd@posting.google.com>
Source record: 133654

Hi,

I am searching a portable antenna to use :
- 1st, abroad, in hotels (on the balconery, through the window, in the field, etc)
- 2d, also when there are too much QRM at home and I want to work in "emergency situations" in a quiet spot outdoor, as they are many in LX or south ON.
and mainly on bands from (40m) 20m to 10m.

There are not many portable antenna (commercial) on the place :
- MP-1, http://www.superantennas.com/___Products/___products.html
- B&W AP10, http://www.bwantennas.com/ap10a.htm
- and last but not least the versatile buddipole, http://www.buddipole.com/
NB. The buddipole exceed twice the price of the 2 first but here is not the question.

What are your experience of these whips and ï¿½ verticadipole ï¿½ as I qualify the last one ?
Some say the MP-1 is better than the AP-10 for Dxing
As SWL (but soon licensed I hope) should it be more interesting for Dxing in the field or in hotels to buy a MP-1 or the latest, or both are useless (I don’t think so) and there are other solutions much more efficient, then which ones ?

(I hope you will confirm the interest of the buddipole, it "looks" great !, and seems to use very nice material - it can for what it cost, $200-350+ according the accessories... -).

The one I've looked at says it is specifically made for 6 meters.

Plans on how to make your own base and mobile antennas, from quarter waves
to beams, quads, and MORE. (These files alone will pay for itself)

UNDERSTANDING coax, swr's, line loss, co-phasing, grounding and MORE. (you
could go to library, copy and forget where you put it..)

CD also includes tuning AND modifications on just about every cb as well as
most 10 meter radios. (for educational purposes) golderscrewdriver is what
$39.95?

Mic wiring to all popular cbs, D104, Sedelata, Turner, standard and of
course MORE. (heck, wanna know whats IN a D-104?)

PLL convertions, adding talk-back, swing kits, roger beeps and MORE
(go to your local shop and ask them to do it, what? more money?)

Packed with pictures, how toos, parts and MORE.

How bout takin a radio and electronics course? FREE
Now includes NTE's cross reference 10.0 program to find over 14,000 parts
!!!! FREE
Schematics, figs, how too's, plus a lot of Amplifier stuff, programs that'll
help you BUILD your own stuff..
need I say MORE?

email for more info, over 130 megs of info in easy to understand format.

Organized for EASY reference.
$20.00

219. Please Help: 20M Mobile XMT Interference -- I hear my XMT audio on stereo speakers even w/radio off

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-05 04:25:01 UTC
From: riffin-rich <riffin-rich@cantspam.me>
Message-ID: <laqspuog7m7vte73jlb6ge1um0v52l61o8@4ax.com>
Source record: 133658

Hello fellow hams. Please help me solve this problem...subject says
it all. 20M appears to be the only band I'm having a problem on...
If I leave my stereo on, forget it... I blast myself out of the truck
with the interference. With the stereo off, I still hear my audio
over the speaker system (very heavily distorted).

Ultimately, I want to leave my stereo on, because I run the radio
output into a casette/adapter to play the radio output across my
stereo. As I said, this works great on all bands except 20M

Setup:
Ford F-250 diesel (no ignition noise--SWEET! ;-)
Icom IC-706, barefoot, 100W
SGC SG-230 Coupler
SGC SG-303 Antenna

Radio is wired to the battery directly...

Thanks,
Rich Seifert, KB2ZMF, Co Springs

220. License plate mount for Hamstick?

Hello. I am considering a hamstick for 6 meters and someone suggested
that I use a license plate mount offered on the hamstick website at
http://www.hamstick.com/Tm-1.html. Has anyone ever used one of these
mounts? Does it require that you use metal screws on the license plate
(I use plastic to prevent rust). Any idea how this will perform with
the 6m hamstick compared to a magmounted 1/4 wave on the roof
(actually, a 2m 5/8 wave, but used as a 1/4 wave on 6m)?

andy
as i told you when i suggested this mount it comes with the required
hardware which includes stainless steel bolts to attach the mount and
license plate you cant use plastic cause it wouldnt hold up to the stress
of the antenna on it
if you would pay attention to what these people write to you you may just
learn something
i am currently using this mount i suggested to you and it is working
wonderfully i have used it with a 102" whip a 17 meter hamstick and
several of the hustler mobile resonators on a 54" mast with no problems
what so ever

sounds like your speaker wires are on the resonat lenght for 20 meters i
would shorten them of get some ferrit cores to wrap around them to stop
any stray RF from getting in
i would suggest going to your local car audio installer and tell them
your problem and see uf they have the cure in stock if not they try
messing with the wire lengths going to the amp and to the speakers since
you are getting with it on and off
good luck

Message-ID: <3d9ea51b$0$18117$edfadb0f@dspool01.news.tele.dk>
Source record: 133666

Hi,
Have been off the waves for a while, moved to a smaller lot, and wish to test a horizontal loop to get on the air, as I understand it is very quiet in respect to man made noise, and as I have difficulties with long runs of wire....

Thought of making a 40m loop, and hope for some performance also on 80m, and even better on the higher bands, but height over ground is a restriction too...so it will be low....say 6 feet above ground.

I want to run coax from my transceiver to the antenna, and find little help in the literature of how to connect the feeder to the loop....any experience out there with you guys?

Does it make sense with the lazy quad, or should I rather go for a vertical, which may also have to stay close to the ground with its feed point? (I have an R5 from previous times, disassembled in the basement)

Tnx in advance,
73's
de OZ6F, Henrik

228. Re: Where to get aluminium tubing???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-05 08:50:11 UTC
From: Les Kramer <wa3sgz@mindspring.com>

Source record: 133667
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc,uk.radio.amateur

Hi Brian,

As a working professional metallurgical engineer in the USA, there are many sources of aluminum tubing available at metal warehouses in the USA. After a quick scan using google, I found that Future Metals (www.futuremetals.com/pages/branches/htm) has a UK warehouse in Hampshire. I don't know where Hampshire is relative to your QTH, but they probably have what you need. Beyond metal warehouses, try suppliers of aircraft materials or aircraft salvage yards for aluminum tubing. Metal warehouses will usually sell small amounts (i.e., a couple of meters), but the cost and cutting charge may be dear.

In the USA, suppliers ink stamp their tubing with an ASTM spec number, and in the UK they probably do the same for the appropriate British Standard. Try to get tubing of the 6061 grade in the T6 or T651 heat treatments (6061 T6 or 6061 T651 Marking) since this alloy is easy to machine, highly corrosion resistant unless it's underwater in the North Sea, easy to weld, relatively strong, and generally available.

By the way, what's B&Q? In the USA, we add another B (i.e., BBQ) and eat it as chicken, pork or beef.

Regards,

Les Kramer,

WA3SGZ

It isn't all bad, even in Britain.

For some years, a village school in our county operated a shopping service that brought in essentials for the local old people who couldn't get into town easily. All the stock control and accounting - including taxes - was done by the primary school kids (2nd-4th graders in the USA).

My wife runs programmes linking schools with the construction industry, right down to primary level, and you should see these kids estimating quantities of materials and numbers of bricks! How do they do it? Because it's really not so difficult, when you get down to it. But what fires them up to do it? Because it's *real* - they're going to see those walls built, right there in their school.

At older ages, young people run micro-businesses in British schools, using real money, and again they take the math in their stride - including Value Added Tax.

Older still, an interior decorator who used to work with my Dad claimed that he was useless at arithmetic. But when he had to estimate rolls of wallpaper, he just went ahead, measured-up and did it. Extra rolls for large patterns with long repeat lengths? No problem - never a roll short, never a roll wasted.

The common factor in all these stories is that when you have a good practical reason to do arithmetic, it suddenly becomes very easy.

It's important to expose young people to the higher concepts of pure math, but realistically it's mostly for the sake of the one in a hundred for whom it really clicks - because we do need the next generation of pure mathematicians [1]. On the other hand, education in basic numeracy for "the rest of us" is too important to be left entirely in the hands of people with math degrees, because the talented can never truly understand why the rest of us don't find it easy too!

Fortunately something is being done about it. British primary (elementary) schools now have a fixed, timetabled Numeracy Hour every day, in an effort to get everybody up to a certain basic level of written and mental arithmetic. Rote learning of multiplication tables is back... because you get there faster if you don't have to work out 7 x 9 from first principles every single time. Calculators are used for some things, but they're banned when developing mental arithmetic skills. Suddenly it's all turned very practical.

Primary school teachers have to cover a wide range of subjects - their weak ones as well as their strong ones - and because this math problem is much more than a generation old, many teachers had some catching-up to do!

When kids are coming out of primary school with some confidence about basic arithmetic, it will give them a flying start into the higher levels of math. These developments will take another 10-20 years to trickle through into the adult population, but I think we will then see some positive results.

[1] Seriously. If you don't believe that pure math is important to a civilized world, then you'd be a hypocrite to use a DSP filter, a digital cellphone or even a CD player - because they're all "powered" by mathematics.

For radio hams, the reason to get into some math - as a first step, the simple arithmetic of Ohm's Law, power and reactance - is because IT MAKES LIFE EASIER!

That's the missing link: just realising that MATH WORKS IN REAL LIFE. It isn't "just abstract theory" - it's a basic part of the real world, and totally connected to it. If you start with real-world facts, and then do some math, the results that come out will be real-world facts too... even if you could never have guessed at them. That's what makes math useful.

Start believing in math, start using it, notice that it works... and it will all come true for you. Promise.

Thierry

I've just been operating from a hotel balcony in The Gambia (C56/G4IRN) using a 10mtr long fibreglass pole with a wire running up it.The pole was mounted on a first floor balcony and I ran a radial, or counterpoise wire, down to a tree behind the room. I centre fed the antenna with 450 Ohn ribbon through an ATU. I guess you could call it a semi vertical doublet? It seemed to work pretty well - I had nearly 6000 QSO's in 5 and a half days of operating..

I have used a simliar set-up with the pole ground mounted and running 4 ten meter long radials out from it. Again, ribbon fed through an ATU. Working with this /P in France I have successfully made QSO's with the Pacific area.

The poles are available from DK9SQ.

It had been used by the virus itself. Somebody has been careless or
naive, but it isn't necessarily any of the people whose names you see.

One of the worst features of these viruses that raid people's address
lists is the way that relationships get soured by blaming innocent
parties. So let's not do it.

Source record: 133571

Dear Thierry,

Try to erase G5RV from your mind. With the best and kindest of motives I suggest you de-brainwash yourself.

Don't buy anything except a reel of 16 or 14 gauge enamelled copper wire.

Erect a dipole of no particular length, as high as possible, which will nicely fit into your back yard. It will do very well if its overall length is greater than about 1/3-wavelength at the lowest frequency you are interested in.

Feed it roughly at its centre with open-wire or 450-ohm ladder line, of no particular length except that it's long enough to come all the way back to the shack with 5 or 10 extra feet to allow for contingencies.

And there you have it. It will be the most power-efficient, multi-band, multi-directional, multi-elevation angle, DX and local, radiating and receiving system possible for your site.

Its beautiful simplicity is an obvious self-recommendation.

But I do not want to deter experimentation. Try the easiest to erect antenna first.

Reg.

I do pay attention. Not everyone on this newsgroup is a member of the
6 meter sked reflector. I am seeking multiple opinions from multiple
sources, not just the opinion of 1 person. I do not base my decisions
to buy things based on *1* opinion. I also read 4 reviews of it on
eham.net and it appears that I may go that route, but I want to hear
from more operators that have used it. Thank you for your reply.

O/T - Free PC tip (especially for those without an antivirus program):

Put this entry into your e-mail program's address book.
Display Name = *virus_trap
E-mail address = <illegaladdressxyz

Be sure to include the '*' and the '<'. This new entry should show up at the top of the list. If an outgoing e-mail message (as created by a virus or worm) happens to include this entry, then it will cause an error and the message won't be sent. A good line of defense, especially considering the cost is nil.

Dennis,

Do you know if suitable mast hardware exists for using this mount with a Halo/Squalo type of antenna for horizontally polarized 6M? I don't see this as being very usefol for a vertically polarized VHF radiator (unless it is used with a mast).

Hello Martin. (You sure have a lot of toys in your shack!)

>Radio grounded to the chassis?

No...I did not know I needed to do this but it makes perfect sense!

>Physical seperation between audio line to the cassette deck and the antenna feedline?

Yes...2 feet from the coax and 4-5 feet from the SG-230 coupler's
"hot" output.

>Any bonding of truck parts to chassis?

No...didn't realize this was necessary given there isn't any other
noise. Will doing this fix the problem I described?

>Where is the antenna mounted?

I have a vertical mount setup in the front section of my truck's
bed...the antenna mount sits about 6 inches below the plane of my
cab's top. Radiation starts about 3 inches below the top of the cab
and goes up 9' from there.

Thanks for your time/help!!!

A quick question regarding ferrite cores...where do I find these
things and install them? Is there a particular part number from a
given manufacturer that you'd suggest?

And yes...just the clatter of the diesel...sometimes enough to get
frustrated...especially while driving and talking on the phone. ;-)
On the other hand, that masculine sound just gets my blood
flowing--especially when I have to start her up in the cold Colorado
mornings--to get her warmed up. I'm thinking it gets my neighbors'
blood flowing for at least 3 houses in all directions... ;-)

Take care,
Rich, KB2ZMF, Co Springs

"riffin-rich"
> A quick question regarding ferrite cores...
> where do I find these things and install them?

The type you would probably want is a small split core type that will fit over a single wire. You'll need a handful of them as it might take several per wire to ensure good results.

The wires in your truck probably won't have enough slack to wind around a larger core, but if they do then that would be better (you should check the available slack - it might change your approach if you have an extra foot in the cable bundle near the stereo).

Where to buy ? I dunno but here is a list of vendors...
http://www.google.com/search?q=ferrite+cores
I'm sure that others will help you to find a source and spec a mix.

I received a lot of messages that told me I was spreading the virus
via the ARRL mail forwarding site. I DO NOT send mail from there, nor
do I use Microsoft's email program. I also use separate programs for
browsing (Netscape), news (Free Agent) and mail (Eudora), so there is
no sharing of addresses.

My ISP also blocked a number of virus containing messages that
supposedly came from people other than hams.

Symantec's web site has a free tool to determine whether you are
infected and if so, to clean your system. Per their instructions I
ran it twice and was clean. Therefore, I couldn't have been passing
it on.
|
|It had been used by the virus itself. Somebody has been careless or
|naive, but it isn't necessarily any of the people whose names you see.
|
|One of the worst features of these viruses that raid people's address
|lists is the way that relationships get soured by blaming innocent
|parties. So let's not do it.

Right on.

Source record: 133582

Hello all,

I'm putting up a center fed doublet to cover all frequencies between 3 and 29 MHz. Have several options available and wanted to know which would be the most efficient feed arrangement for my automatic tuner.

1. Tuner at feedpoint with one leg attached to the antenna terminal and the other leg attached to the ground terminal. The tuner is left "floating", not grounded and I assume some type of isolation (ferrite beads) on the coax should be added to prevent a return current on the braid.

2. Fed with autotuner to balun attached to the antenna.

3. Feed the center of the wire with the output from the tuner. (no breaks in the antenna) Am I nuts for even suggesting this one?

4. My favorite - Autotuner at ground level feeding a balun with a short run (less than 30 feet) of ladder line to the antenna.

Thanks,
Ken N4VSD

At 6foot above ground you will have a straight up radiator, if you can get it to resonate at all.

I would suggest you use ladder or open wire feed. Run it into the shack to the tuner. Better yet put a balun outside and run the coax into the house into a tuner. Feed it where you feel good.. corner or the middle. Since its horizontal with the other limitations I doubt it would make much difference.

While tubing (and wood) is not sold in inches in the UK any more (thanks to those bloody Europeans making it illegal to use non-metric measure in EU states) it is still available, it's just labelled in the metric measure. So inch square tubing is 25mm (nom). The (nom) after the 25mm is for nominal, and allows for the difference between 25mm and one inch. It's a bit hit and miss though. I bought three lengths of inch square aluminium tube for an antenna project and found a pronounced difference in the size of one (bought from another supplier) to the other two.

Metric equivalents of imperial measures are only readily available for those things that were "standard" imperial measures, like 4" water pipe, 2"x4" wood joists etc. Unfortunately these old standards are slowly being eroded in favour of close metric ones. For most imperial measurement, the nearest metric size will usually do the job OK, the difference in size will be less than the usual tolerances accepted in hand measuring and cutting.

I found a rather sturdy vertical antenna at the tip a while back which had a n type female socket for the coax. This lead me to believe that it is for the microwave spectrum. I have 2.4ghz wireless access point for intranet connectivity and was wondering how would I go about testing this antenna and finding out its frequency range? I have it plugged up currently and the signal coming from it at 2.4ghz is good, but Im not entirely sure it was designed for that frequency.
Thanks,
Aaron.

Henrik,

It depends on your needs for local or DX operation. Multiband operation would best be handled by open wire feed with a link coupled tuner, or double balanced tuner, in the shack. Another alternative is to use coax with a 4:1 balun at the feedpoint.

73s,

Evan

From: tmgroatatpeakpeakdotcom
Message-ID: <3d9ef98d.1383891@news.peakpeak.com>
Source record: 133592

Adding on to Roy and Reg's comments, there's one more factor that makes the higher impedance lines better for multi-band antennas.

The antenna feed point impedance of a wire antenna over ground will range from a low near 50 ohms (or less for very low wires) to a high of thousands of ohms. Consider how that high impedance translates through low and high impedance feedlines:

5000 ohm antenna, 50 ohm line, SWR = 100:1. The impedance on the line ranges from 0.5 ohm to 5000 ohms.

Same antenna, 500 ohm line, SWR=10:1. The impedance on the line ranges from 50 ohms to 5000 ohms.

A feedline near the geometric mean of the antenna impedance range has moderate SWR all bands. It prevents very low impedances from occurring anywhere on the line. This reduces I^2R losses, and is less likely to be outside the transmatch's adjustment range.

So to answer your original question: either 450 or 600 ohm line works well with a multi-band wire antenna (and so would 300 ohm line).

==========

Can't see how the above will work. No virus would be stupid enough to
include that entry.

Or have I missed something ?

>Right on.

So let's nail the principle culprit - Windows in whatever form and
design dominated by marketing.

The local (Seattle) paper's business section continues to announce new
major security breaches in MS client and server software. Warnings
have come twice-a-week average for some time now, and weekly for a
year before that.

MS has had major problems with their Passport service revealing
personal data to simple attacks. MS has also lost its third party
designer base to Java or other languages run on Linux. Microsoft's
.NET has failed to attract designers who perceive numerous security
issues.

Chairman Bill pronounced a war on insecure design about a year ago.
Skip forward that same year: low and behold they have a trade show of
their PC of the future (about 5 years away) which reportedly lacks
security features. The artwork shown in the paper features the glazed
expression of the owner sitting about 2 foot back from a 2' X 4'
display curved like a windshield (actually quite radical, about 60ï¿½).
The subtle implication is that the office cubicle will soon shrink to
the size of a desktop holodeck.

I once recall an incident in installing Windows 3. I had already been
a part of the their beta test, so I knew my system was up to the
install. Such smug hubris is inevitably cracked by Microsoft and as
testimony, the installation refused to acknowledge my mouse existed.
It's always the low tech problems that cripple you. Stumped by this
obstacle, I called MS support and we spent an hour re-installing
Windows to arrive at the same report: Mouse does not exist. The tech
asked what kind of mouse I was using. I replied a Microsoft Mouse.
Bingo! The tech dryly reported that Windows did not support my mouse
- and he was right.

A double-sized G5RV is designed for 40m and also works well on 80m & 160m.
A regular-sized G5RV is designed for 20m and also works well on 40m & 80m.
A half-sized G5RV is designed for 10m and also works well on 20m & 40m.

Oh, come on now! Any operating system is susceptible to viruses. It
just so happens that most people are using Windows and therefore if
you were making virus to affect as many users as possible then it
makes good sense that the Windows operating system would be the best
candidate.

Henrik,
The cinnections are between one end of the loop to the
center conductor, the other end of the loop to the braid.
While loops tend to be 'quieter' than verticals or a
dipole, do not expect it to be very much quieter. The
difference is noticable, but small. With the restrictions
you have as to height, and the use of coaxial feed line,
I think you may be happier with the 'R-5'. Feeding the
loop with 'ladder line' through a tuner would be a 'better'
way of using the loop on other bands than the one it is
designed for. The impedance on other bands is easier to
handle with a tuner and ladder line.
A 40 meter loop on 80 meters, for example, is not a very
satisfactory antenna, no matter what type of feed line is
used. It can be done, though, and naturally, any antenna
is better than none.
Good luck...
'Doc

For exactly those type problems, I use Amidon FT-150A-F toroids.
My mobile amplified speaker was noisey during transmit. One of
these toroids cured the problem.

Not only Windows, but Microsoft products in general. I use Netscape
4.7 which seems to be relatively immune from viruses designed for
Microsoft products.

> course in the lower ones too, 80-40m to 10m, in the winter).

I just modeled a double-size G5RV using EZNEC. It is a 204 ft dipole fed with 58 ft of 300 ohm twinlead (VF=0.9). As I suspected, the antenna does a good job on 160m, 80m, & 40m. The SWR's on the 50 ohm coax are 4:1 on 1.95 MHz, 4:1 on 4.0 MHz, and 2.4:1 on 7.19 MHz.

SWR on the 50 ohm coax is 15-20:1 for all higher frequency HF bands except 20m where it jumps to 57:1. This is not a good antenna for HF ham frequencies above 7.3 MHz unless one is using a very short run of ordinary coax or very low loss (expensive) coax.

The regular-size G5RV works well on 80m, 40m, 20m, & 12m and marginally on 15m, but the 50 ohm SWR is too high on 30m, 17m, & 10m.

Reg gave some pretty good advice. Put up a 1/2WL resonant dipole on your lowest frequency of interest, feed it with ladder-line, and have an all-HF-band antenna. You may have to adjust the feedline length on certain bands. Such an antenna is presented on my web page and requires no conventional antenna tuner.

Reg,
That entry in your address book will stop most
virus programs that use your address book to resend
it's self. That entry, or one simular to it, will
cause your email program to stop for an error, then
notify you that there's a problem. It's still up to
you to 'cure' the problem by running an anti-virus
program or whatever. All the entry does is prevent a
virus from sending email. You still have the virus.
'Doc

No this was not meant to be denial. It was meant to say that if we all switch to Netscape, the problem will come back because now the authors of such viruses will go after it for maximum effectiveness. Switching to Netscape would actually be a form of denial that wouldn't work for long.

I keep my anti-virus software up to date and never open any attachments that I didn't specifically ask for.

Linux Rules!! any OS may be susceptible, but MS tends to deny there's
a problem at first - like in the case of the Nimda virus - the only
one that comes to mind since i don't have time to read everything.

Per "In The Trenches", a column in Linux Magazine about a year or so
ago, the Linux kernel team, on the other hand, responded to and fixed
a vulnerability within 24 hrs. the problem was brought to their
attention by a programmer who just decided to see what would happen
if he sent a malformed IP header.

I like that story about MS not supporting their own mouse. If that's
true, it's crack addiction at it's finest.

OT:

I just love MS's updates, too. I haven't determined the exact
problem, but between MS IE 5.0 thru 6.0 along with MS Visual Studio.
The latest MSDN library, which is HTML help, doesn't work. But the
MSDN library from years ago does. Well, I guess I don't need all that
.NET BS anyway. Problem is, the new MSDN CD files have an extra link
for API functions that tells you what header to include and what
library to link.

And you can't uninstall IE6.0 to revert. It seems that after updating
IE, a Visual Studio install trashes it with previous IE files. So I
think you have to reinstall the whole OS, Install VS, then do the IE
update because IIRC, the IE update is what got MSDN working again for
me after who knows what trashed it in the first place.

Hi Reggie -

It's not clear which W9INN antenna you intended to use in your comparison.
He has a couple of dozen standard models, plus an indeterminate number of
custom variations. His most popular designs are the MPD-5-xx models,
which include 80m. But if you want to compare to a smaller design that
only goes down to 40m, then the SSD-045-xx might be the one. It covers
10m, 15m, 20m, and 40m.

I have an MBD-847 (17m, 40m, and 80m) hung as a LOW inverted vee:
The center is about 28' up, and the ends about 8' up. It's also folded into
a 60-degree vee (ouch!), because that's all the space I have.

It works extremely well on all three bands, notwithstanding the severely
compromised installation. In fact, a net control on one of the big 80m nets
out here said I was so loud I should sign up as one of the net controls!
Maybe he was just trying to share the work, though. ;-)

So if you are correct in accessing the performance of your G5RV Junior
as "lousy" on some bands, then YES, you could expect the corresponding
W9INN to outperform it handily. This would not be surprising, since
the W9INN uses a more complex design, with fanned elements and traps,
to achieve true half-wave resonance on all bands (most models).

Yes, yes, yes!

But computer user's mindless insistence that all computers must be running the same software, and that they be running the same essential platform, is just not very clever.

I use Netscape specifically *because* there are not many virii written for it. If so many people switched to Netscape that the bad guys wrote virii for it, I would change to yet another program.

I have to shake my head at all the poor people who insist on using the poorly written (popularity is only one part of the problem) programs, spend much time trying to stay ahead of the bad guys, then inevitably fail.

It doesn't have to be that way.

And I think if people didn't just buy MS software because they are the "standard", that MS might actually have to write better software.

<dee.hays@sbcglobal.net> wrote:

>No this was not meant to be denial.

Saying "no" that it is not denial is a classic self-fulfilling
example.

>It was meant to say that if we all
>switch to Netscape, the problem will come back because now the authors of
>such viruses will go after it for maximum effectiveness.

And this is further denial in that Netscape offers no vectors
similarly presented by the Microsoft security lapses. Netscape is not
integrated with the desktop and it is THAT integration that is the
security problem, not any particular or isolated executable. In this
sense denial comes in the form of compartmentalization of the problem
to explain it away, and it is this compartmentalization that leads
exactly to the blindsiding that serve the virus writers so.

It further denies the obvious lack of concern: Microsoft doesn't
perceive this as their problem. This is most obvious when they whine
how it is our fault for poor security settings (it's all there, but we
as customers are just too stupid to configure it correctly). Blame
the customer is poor service and is no defense for doing nothing.

Projecting the problem into terms that Netscape "could be" attacked is
specious. All systems suffer the same potential threat, again, the
survivors already exhibit a solution and the failures exhibit a
problem. Saying the survivors are at risk while holding onto failure
is denial in the extreme.

> Switching to
>Netscape would actually be a form of denial that wouldn't work for long.

This is denial through automatic rejection. I have never suffered any
attack through Netscape and the idea that this will not hold long
simply does not track history nor the respond to the actual evidence
of what fails (MS) and what does not (Netscape).

>
>I keep my anti-virus software up to date and never open any attachments that
>I didn't specifically ask for.

That is commendable, but really only offers virus protection through
autopsy when you should be tackling the problem and not the bug.
Proving you can find the virus in the corpse does not bring vitality

back to the dead. A virus cannot exist when it cannot sustain itself. Microsoft design is chock full of sustaining mechanisms that keep these bugs active. This has been most manifest and reported on a twice weekly basis for the better part of the last year. How many service packs have you downloaded? If your only activity has been confined to picking nits off the crashed system - you have insured your future activities to an endless cycle of repetition.

The simple fact of the matter, already identified and admitted to by Microsoft, is that if you want a secure IE browser, you have to turn off most the features. If you have not done this, you are in denial. I have seen some crow about how they have performed their security settings (which Microsoft implements to default to the most insecure configuration) - and their cozy denial is in ignoring that Microsoft security is broke (as glaringly evidenced by those same twice weekly announcements). It doesn't matter what your settings are anyway, they don't work! Or worse, some work - guess which ones?

Denial is most obvious in users of MSIE when they ignore the hundred-odd reports of security violation (and never perform the fixes), they don't maintain their security settings, and they still run full-featured. This probably covers only 99% of the Windows user population. Only Anderson bookkeeping could turn this into a positive reading - and to the same results, catastrophic failure guaranteed.

Source record: 133524

A lot of the common viruses get addresses from the victim's address book to send copies of the virus to. They fake the headers to conceal the real source of the message, in a manner similar to that used by spammers. Often, the "From:" portion of the header contains the email address of someone else fished from the victim's address book, and other than that, bears no relationship to the unwitting owner of the machine sending the virus.

There are several things everyone can do to reduce the spread of these viruses. One is to prevent yourself from getting infected. NEVER open an email attachment unless you know for certain what it contains. If you're in doubt, email the sender for confirmation before you open it. Also, in your web browser options, make sure that JavaScript is turned off for email and newsgroups. This prevents an email message from inserting a virus even without your even opening an attachment. Careful users also turn off JavaScript for web browsing, and turn it on only when needed and when visiting trusted sites.

Today's anti-virus software can be set to scan email messages before you open them and alert you if a virus is detected. Get and use an anti-virus program, and keep it updated with the latest definitions. Do a full virus scan regularly. Two of the most popular are Norton and McAfee.

Another step to take is to install a firewall that monitors both incoming and outgoing Internet activity. There are many "back doors" into your system. Hackers can use these to implant software on your system without your knowledge that can be used for spreading viruses, sending spam, launching denial-of-service attacks, or acting as a remotely-controlled computer for any purpose. People with DSL or other high speed connections are much more vulnerable to "back door" entry, but even modem-connected users can be victims. A firewall that monitors outgoing activity will detect when an implanted virus or other pernicious software attempts to transmit, so is an added line of defense. A number of good firewalls are available. One of the better ones is free, so no one should be without one. You can get the free version of ZoneAlarm at http://www.zonelabs.com/store/content/home.jsp.

When you do receive email with a suspect attachment, you can help prevent its further spread by notifying the sender. Remember, the real sender probably isn't the person shown in the "From:" or "Reply-To:" lines of the header. But there's a great service called SpamCop that can go through a header and identify the actual sending ISP, even when the header has been faked. To use SpamCop, go to http://spamcop.net, then click "Overview of Services" under "Services", and register for the free service. Once you're signed up for the free service, use your browser to

view the email message source, which shows the entire message including the header. Select and copy this entire message to the Windows Clipboard. Paste it into the SpamCop window and have it analyze the message. When it's finished, the first reporting suggestion will be the source of the message. BUT DON'T USE SPAMCOP TO REPORT THE VIRUS -- IT SHOULD ONLY BE USED FOR REPORTING SPAM. Record the suggested reporting address, and click "Cancel". Then compose an email message to the reporting address. Explain that the email message contains a virus, and ask that the ISP notify the individual sender (which they, but not you, can identify) that he's sending a virus. Include in your message the entire email message you received, including the full header. (This is the same thing you pasted into the SpamCop window.) The header is vital, since it's what the ISP will use to determine the individual sender.

And now that you've signed up for SpamCop, you can do us all a favor by using it to report all the spam you receive.

Folks, it's the Wild West out here in cyberspace. There're no lawmen looking out for you, so you've gotta wear your own six-gun. And never sit at the bar with your back to the door.

As it's taken 15 or 20 years to write Windows it will take another 15 or 20 years to re-write it.

The Internet must eventually be placed under internationally agreed control in order to eliminate virus's and spam.

Unfortunately this means Big Brother.

If the ferrites don't do the job, try to get the antenna to the back of the truck, at least temporarily for a test. You may have fundamental overload and/or rectification happening because the stereo is in the near-field/max rf from the antenna. Physical seperation might help.

I can't use 17m in my Jeep without the automatic tranny shifting gears on cw.

hey tam
this thing was designed more for HF and 6 meter hamsticks
i have not seen anyhting like what you are asking about
i used it with a 102 inch whip for 10 meters and all of the hustler resonators on the 54 in mast
but that entire mast resonates i believe not justb the tip so if you took one of hustlers M0-1 54 in masts and attached a halo i think it would mess up its pattern

290. Re: G5RV, single or double length ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-06 03:05:03 UTC
From: Roger Appleby <rappleby@ihug.co.nz>
Message-ID: <ano9d4eko1@lust.ihug.co.nz>
Source record: 133529

I would echo the feeling of at least one other reply in that get rid of the
G5RV thoughts and go for a centre-fed dipole with open wire feeder.
I started with a G5RV (1/2 length) and it worked very well on 20m but on
other bands not so well.
I then converted it to 66ft overall length (2 x 33 ft) and fed it with 450
ohm open wire feeder. The feeder length shouldn't be important but it is in
my configuration..it's about 10m in length. This is then tuned by a MFJ941
into the internal 4:1 balun.
It works very well on 40m, 20m,17m and 15m and reasonably well on 12m and
10m when things are happening.
But as echoed...experiment as your surroundings will also come into play and
may influence one set-up more than another!
Good luck!
Roger

Doesn't need re-written. Needs discarded and something else put in its place.

I was aware of this years ago when I started in computers with an Amiga, and learned enough that the "standard" system was broken. We've "improved" that broken system through the years, mostly with faster and faster processors, but it's still broken. As some in the States say, "You can't polish a turd!" ;^)

> The Internet must eventually be placed under internationally agreed control
> in order to eliminate virus's and spam.

This is what some would have you believe. Unneeded "features" that expose the innards of your computer to outside manipulation automatically place it in a vulnerable position.

Lets look at a "feature". Someone decided that it was too much trouble to type your credit card info into a web page when you were trying to buy software or whatever over the web. So they come up with a whiz-bang system to store your info on your computer, or even better on *their* server. Sounds good.

Problem is that for people who do coding, it isn't all that difficult to get into either your computer or theirs to find this out. Not to mention, it isn't too good to trust your cc information to be sitting on a server.

Now it is very true that we have to give out our number from time to time over the phone or an encrypted web page. Those are fairly safe tho'. Having it sitting there on a server is like dangling a big fat carrot in front of the hacker bunnies. and there is the difference.

292. removing busted bolts from bottom of tower

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-06 03:12:51 UTC
From: Dave Benham <dodgeboy@mindspring.com>
Message-ID: <ano9k7$j9d$1@nntp9.atl.mindspring.net>
Source record: 133530

I picked up an old tower that was probably originally designed for TV, CB or very light ham use. It's aluminum and all the cross braces are put together with bolts and nuts, not welded. At the bottom of the lower section there are two holes in each leg. Two legs have these holes lined up on the same axis, so those legs can be bolted to the base and the tower walked up and the final leg bolted in. All I wanted it for was as a way to raise an R7 up higher.

My problem is that two of these total of six holes have broken off bolts inside them. The bolts are broken flush with the tower leg so there's nothing to grab onto. The bolts are steel and they pass through some sort of reinforcement metal inside the tube of the leg -- I'm not sure what this material is. I've drilled holes in them and tried an easy-out -- no luck whatsoever. They don't budge. From the appearance of the other clear holes, I don't believe these broken bolts are threaded through the holes -- there may be threads on the bolts, but not in the female portion it passes through. I've applied heat with a fine tipped OA torch with no luck -- that's tricky because of the nearby aluminum -- too much heat and there goes the tower leg, so I may not have applied enough heat. I also tried Liquid Wrench -- no luck.

My holes in these bolts are not perfectly on center, so it would be almost impossible for me to drill out the bolts without enlarging and elongating the hole itself. In fact, one of the bolts is so hard that I can't get a drill to pass through it. The bit just spins. I resharpened the bit, and still no luck. I got a good way in from both sides of this bolt, but there is some sort of hard spot in the center that I can't get through.

I am about to cut off the bottom 4" of each leg and start over, but then I'd be faced with drilling the holes on the 2 legs perfectly in line which would be very difficult "in the field" (the tower won't fit in my basement where the drill press is!).

Any ideas?

Thanks.

From: Tom Smith <end@spam.com>
Message-ID: <anoci3$9h$1@slb4.atl.mindspring.net>
Source record: 133533

About 10 months ago I saw an email in my inbox with a subject line having to do with coax---Coax Loss---or some such topic. I was very alarmed when I saw it and suspected it to be a virus---I had no memory of participating in that thread of discussion. I suspected it originated from this newsgroup whereupon I attempted to find the message in the archive before doing anything else. I found the thread and it all seemed harmless---just a short, routine discussion on some aspect of coax. My memory was correct, I had not submitted to the thread---as a matter of fact, I think I even left the newsgroup before the discussion took place.

I figured I would open the email---WRONG! I loaded my system with a Trojan horse and a virus that started to send out emails to my friends and folks I never heard of before. Thankfully, a number of those recipients emailed back telling me that I had a virus---I shut down the system. Odd I thought, I don't even have an address book---I type in the addresses manually on the emails I send and I keep my folders cleared of accumulating emails.

I wondered why I got this email/virus in the first place. Studying the thread I found only one commonality---Reg Edwards had responded to the 'Coax' thread and I sent a personal email to Reg about a year and half ago (well before the thread). I suspect in some way this was the path the virus took to my computer---NO BLAME IS BEING PLACED ON REG FOR THE VIRUS. With the help of a specialist at the university we analyzed the key logger.

Have you tried blocking the tower leg off the ground and driving them
out with a hammer and a punch just smaller than the bolt diameter?
Sometimes a soft but sharp blow is needed to loosen 'frozen' bolts. Of
course care must be taken to keep from damaging the aluminum, and that
may be the catch here.

Dick

CAM, where do you get the Amidon FT-150A-F toroids? And what exactly
do they look like? do you have to cut a wire and wrap it or do these
things just slip over the wire? Where did you put them? One on each
of the two wires going to the speaker? Or one per pair of wire?
Thx...

298. RFI problem with TOUCH SWITCH

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-06 04:54:57 UTC
From: Leland Cox <lcox107@comcast.net>
Message-ID: <3D9FC221.5030803@comcast.net>
Source record: 133537

My wife has several lamp s with touch switches. When I try to transmit on HF with even low power, the lamps switch on and off!

I am using an Icom 706 Mk2G. I had a TVI problem on 2M and 440 but found a bad cable causing that problem.

I have a bunch of ferrite chokes on the power wire for these lamps. Not much help!

No problem on the dummy load!

Anyone have an answer to this problem other than removing the touch switches or divorcing the XYL?

Les, AA4F

Les,
The capacitive circuit the 'touch' lamps use makes
a fantastic all band antenna! Unfortunately, without
a lot of work in the lamp, there isn't much you can do.
The chokes, as you found out, won't help at all. There
was an article about 'touch' lamps in one of the mafazines
a while back, sorry, I have no idea which one. Not a lot
of help, huh?

Dave,
I think you may be on the right track by cutting the
legs off. It may be easier to make a base plate that
will bolt to the shortened tower section to act as the
hinge. It shouldn't be that difficult to make the base
in such a way that the holes in the tower legs can be
drilled using the base plate as a template.

Please be careful about using SpamCop as your bodyguard - it's too trigger-happy, and some of the ricochets can come right back at you.

One of the things SpamCop can do is block mail from IP addresses that have been used for spamming. "Great!" you say... but what actually happens?

If some idiot tries to use *your* ISP to send spam, your ISP can only shut them down after the offence has been committed (or is in progress). Some spam will get out, and if SpamCop notices, it will then target *all* mail from the offending IP address. But that address is usually an outgoing mail server which is being shared among all of your ISP's customers - including *you*.

So any of *your* outgoing messages that happen to be routed through that server will not reach anyone who is "protected" by SpamCop. It takes several days before a timer inside SpamCop graciously decides to "forgive" your ISP.

IMO, this particular cure is worse than the original problem.

==========

Hello Leland,

At HF, loading coils contribute towards total radiation in direct proportion to their length. Or, if you like, height.

The following programs take length of loading coils, and current distribution versus length, into account in their analyses. Skin and proximity effect is taken into account by entering coil Q. Coil Q can be estimated with sufficient accuracy by using program SOLNOID2.

Download in a few seconds programs HELICAL3, VERTLOAD, LOADCOIL. All deal with short, loaded, vertical antennas, either in back yards or vehicle mounted. They will tell you most of what you want to know except the radiating pattern of short verticals which everybody knows already.

Between them they differ mainly in what data is input and what is output.

Enter dimensions of your antenna to obtain radiating performance estimates, feedpoint impedance, etc. Sometimes tuner L and C values. "What if ?" data entry.

sorry, but with klez or bugbear it won't work. those viruses don't just use your address book, they raid other files that have addresses in them. they also run their own smtp engine that bypasses your own mail software so it won't stop just because you try to bugger up your address book. this worked on some of the early mass mail viruses but this 'fix' has been so well publisized that any virus writer out there is sure to have bypassed it by now.

these virus don't just work on your address book, they take addresses out of mail you have sent or received. so all it takes is for someone who has received the messages from the group, read a newsgroup, or in any other way has your address on their computer and the virus will use it. worse yet, they randomly select not only the 'to' address which sent it to you, but also the 'from' address so you can't tell who it is coming from, and this bugbear apparently copies subjects and snippets out of other messages to make them look more realistic.

the best defense against these virii i have seen is to have an isp that scans mail before it even gets to you. my current isp updates their virus scan lists like every hour or so, my virus software hasn't seen a virus come in for a year or more now. all i get are these messages saying the contents were infected and removed.

OD = 1.5", ID = 0.75", Hgt = 0.5" typical toroid

How you wrap them depends on whether it is a differential problem or
a common-mode problem. Most problems are common-mode. I put about
ten turns of speaker wire on the toroid, then cut the original speaker
wires and crimp the choke into the circuit close to the speaker
using automotive butt terminal lugs.

309. OT: WinXP v. Win98

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-06 14:42:32 UTC
From: Wes Stewart <n7ws@nowhere.com>
Message-ID: <2si0qu0vej2q6ckmkv2j24ik7svohbbovp@4ax.com>
Source record: 133548

Sorry to be OT but since there are a lot of computer savvy folks here I figured I'd ask a few questions here instead of some group where I would be a newbie.

Is there any compelling reason to migrate to XP (pro) from Win98? I'm in the process of "upgrading" but I feel "degraded" instead.

Note: "Stability" is not a compelling reason. The latest example I observed of superior stability was when the XYL asked me to drive her someplace and I told XP to shut down the computer. It dutifully popped up a screen that said "Windows shutting down" so I left. When I returned four hours later, it was still "shutting down." But maybe that's what Bill Gates means by stable.

Half of my software doesn't work with XP, and of the half that does often I have to install it twice on the two "virtual machines" that I've tried to set up.

I used windows update to install Service pack 1, which only took four hours to download and install and it appears that if I blow away the operating system and want to reinstall it I get to do the four hour drill again because the service pack wasn't actually placed on my hard drive for backup.

I put this on a new hard drive, which I partitioned into two logical drives. According to the best info I could find I first installed Win98 on one partition, then XP on the other. XP then made a boot.ini file that is supposed to allow dual booting. Not on your life.

I previously used Zone Alarm with Win98. Is the XP "firewall" adequate or do I need Zone Alarm too?

I seem to be spending half of my waking hours maintaining a computer, which is supposed to be a tool, not an avocation.

Should I buy a Mac?

73,

Wes

Any way to keep the tower cool while you torch the bolts out? Try
wrapping wet rags on all the nearby metal as close the the bolts as
you can get. That "should" keep it cool enough to keep from melting if
you work fast. I'd get everything wrapped in wet rags/towels, and
blast it out with the torch. A cutting tip would help, but if you
don't have one, just crank up the oxygen when it's red hot and you are
ready to blast it out. If that doesn't work, you may have to cut the

legs off.

QST had an article that an individual wrote how he solved this problem. It was about 3 to 4 years ago so you should be able to go the the ARRL site and search on "touch lamp" and capacitor. The solution was to put add a capcitor to the input power and switch.

I would double check all grounds. I've seen this problem on my 706 when I had a marginal ground. Mainly at the antenna base. I was mounting on the front edge of a truck bed, and ended up not really having enough metal under the antenna. I moved it to a different spot, and it mostly cleared up. I think I had this problem the worst on 17m. I'd ground the radio, antenna base, and make sure all grounds tie to the frame of the truck as a common point. Also double check your power wiring. Make sure it's thick enough wire and well connected. MK

Hello,

While I do not have "empirical" evidence concerning the efficiency of screwdriver antennas... Can share some anecdotal evidence... A top loaded mobile antenna (Hustler) or whip using an automatic tuner is the best way to go. A screwdriver antenna is a very lossy device and your radiation efficiency will suffer. Ask one of the screwdriver antenna manufacturers about their field strength measurements versus a top loaded hustler. The usual response is... you can tune it from inside the car, I've worked a 100 countries, (those of us with the more efficient mobile antennas have probably worked 300 in the same amount of time!) and look at the wonderful SWR!! Sure, the SWR is great... So is the SWR into my dummy load. I would recommend spending a few extra dollars and investing in an automatic tuner with a mobile whip. In the long run this arrangement is probably more cost effective (screwdrivers are prone to breaking due to vibration) and a much more efficient than a screwdriver. And, a much safer means of operating while driving. Our eyes should be on the road not the swr meter. If the budget cannot support an automatic tuner, purchase a top loaded mobile whip for two or three of your favorite bands. If you can stand ugly the Texas Bugcatcher is an excellent choice as well. It's fun having the guy at the other end give you an excellent signal report and then tell him your mobile. Whatever antenna you buy be sure to have an excellent grounding system and the base of the antenna as high on the car as possible. The two worse culprits for a bad mobile install are poor grounding and the antenna in an impossible place to work efficiently.

318. Ideas? Trying to Extend Power From Battery Into Vehicle's Interior

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-06 16:02:15 UTC
From: riffin-rich <riffin-rich@cantspam.me>
Message-ID: <b9l0qus5t70cupehfl92h045l8rf995qv2@4ax.com>
Source record: 133556

Sounds simple enough, but how do I cleanly/professionally accomplish it? I've been to Lowes, Home Depot, a couple of auto parts stores and auto-electronics install shops and found no ideas worth pursuing...

My desire is to use some really heavy gauge wire -- I'll need about 16' -- (what gauge will I need for this kind of a run?) -- enough to handle current to support all radios and the linear amplifier to extend power directly from my dual battery/dual alternator engine compartment into the truck's interier. From there, I want a really clean power distribution strip/bar or something better than crimp-on connectors fastened together with 3/16" nuts/bolts (suggested by all the places I was at before).

As far as radios, I'll be using two primary radios: an IC-706 and IC-2070 (when they finally release it). I don't have the 500W linear amplifier yet, but I intend to add it to my setup at some point in the future and I'd like to use existing wires unless you all don't think it's practical...

Thoughts / Suggestions? Many thanks....

Source record: 133557

What is the length of the antenna? And, does it have a model number or manufacturer stamped on it? If it wasn't designed for 2.4GHz it will eventually fry anything hooked up to it. As far as determining it's frequency without some type of marking on the antenna is going to be difficult. Ask around in your area if there are any hams using microwave or Oscar-40, they should have a means of measuring it. A picture would help if nothing else.

Wes,
That's odd, I'm using 'XP' and am having no trouble
with it. In fact, except for the period of time it
took for me to 'un-learn' W98SE and learn 'XP', I honestly
have to say this has been the most 'painless' up grade,
and operating system I've used.
As with any version of 'Windows', the more memory you
have, the better it works. The 'average' suggested memory
amount that MS recomends is the absolute minimum you can
'get by' with, the more the merrier. Also, the more things
'registered' on the computer (in the registery), the slower
it is. Even with a 'slug' of programs, my 'XP' is still
faster to start/stop than '98 was, and if you really want to,
there are 'tricks' that make it shut down almost as fast as
flipping the switch (well, sort of).
I have to agree with you that Mr. Gates, or the designers
at MS, need to quit worrying about making things 'new', and
start polishing the operating systems they have now. The
'holes' that they seem to design in, need to be filled. There
are 'better' OS's, but 'Windows' is the easiest to live with
as far as convenience is conserned...
'Doc
PS - What can you say about any company that considers a
keyboard an accessory?

JustThinkin,
About using a 'Match Box' on 160 and the WARC bands, all
it needs is to add in switchable capacitance (a door-knob or
two). I haven't done it, but have seen a couple done locally.
Really, the only thing going for the Hohnson MatchBoxes is the
link coupling. 'Course, that's enough, huh?

Rich,

Personally, in my car I used 6 gauge wire, routed away from any moving parts (I have had people come into my shop and ask why their amp wasn't working, and when I looked at the wiring, lo-and-behold!!! Wire caught in the cruise control motor (older s-10 with vaccuum motor)), drilled a hole through the fire wall (be sure to check for wires and other stuff on the other side!), put a grommet on the wire (keeps wire away from the edges of the metal that will chafe it and cause a short and keeps cold wind out of the car), run it up into a distribution block (4 connections is good, I used 8, since I never know what new toys I might get in the future hihi). Since it is a truck, and an ic-706, use the remote kit in it, and put your radio under the seat, making sure it has enough room for cooling, and run your distribution block back there. Make sure the block can't be messed with though, since you have around, and this is a guess, 1600 amps or so running back there, since you said you have a dual batt., and I am guessing they are in parrallel. Any other questions, e-mail me, and I will give you pics of some of the installs I have done. A couple are ham installs, most are high current car radio (total of 4000 of amps needs a lot of power!!).

Source record: 133563

Hi Wes. 3 months ago, I built a new system--a 2.4GHZ P4 with 1GB RAM and twin 120GB drives...even more bells and whistles as it pertains to Audigy Platinum sound, 48x readers/writers, etc... I thought it was best to install Win XP Pro (the state of the art OS to complement my state of the art H/W).

Let me define a problem using a common legacy program, Office 2000 or previous. Win XP needs Office XP to run "properly" if you want to follow the ideal security model. The point of Win XP Pro was to allow an administrator to install the software and create user accounts with limited permissions. The limited user accounts would then log on and use the system without having full-up sys admin priveleges, thereby limiting the damage they could cause if they encountered a virus or if a hacker somehow ingressed the system while they were on-line.

Office 2K, like its predecessors, doesn't follow the newest/strongest security model of XP-certified software. While Office 2K works great as when you're logged on as an administrator, it doesn't work great if you log on as a limited user. That's because the Office 2K software is trying to write to directories (and the registry) which Win XP has locked down. While there are ways to fix this problem so that it can work for a limited user, you're ultimately compromising the intent of Win XP Pro.

For what it's worth, I have an always-on 4+Mb/sec connection to the internet. So, security is important to me...but because I'm not running all XP compliant software, I'm actually comprimising security. (I do run a h/w firewall, ZoneAlarm, and I check for antivirus updates DAILY...).

Also, your slow shut down is based on using legacy hardware and/or drivers and/or software. My shutdown was screaming fast...under 5 secs until I installed my old smartmedia card reader. Now shutdowns take nearly 2 mins...but I won't pay for a new one because this one works for the limited applications.

Bottom lines: (1) If you're going to use non XP-certified software, and you're not terribly concerned about maximizing your security model, then you're probably better off using Win 98SE. (2) If you're using Win XP and going to use log-on as an administrator all the time--you probably don't need Win XP Pro because you're not fanatically concerned about enforcing security (my opinion...no flames intended...) (3) Do not, repeat, do not rely on the very limited Win XP firewall. I suggest disabling it altogether and running Zone Alarm (far more comprehensive a solution).

Enough for now. Good luck with your tough decision.

Regards,

Unfortunately Ian is quite right about this. My otherwise excellent ADSL provider, Telus, regularly gets put on the SpamCop list for this very reason, and outgoing mail from my computer or my wife's computer then gets returned from some ISPs. Fortunately, fewer and fewer ISPs are paying attention to SpamCop. At one time, Telus had two different machines acting as SMTPservers, with different IP addresses. Depending upon the luck of the draw, a given e-mail message would go out through the first machine (IP address not blocked) or the second (IP address blocked). If a message bounced, we'd just try again.

SPAM is a very real problem. But many of the cures are even worse than the disease. The "Delete" button is cheap and effective and if you throw something away that you should have kept, it's your own fault. My wife and I have to use it an average of 50 times per day, and this number is increasing rapidly with time. SPAM is even more a pain in the neck when away from home and using a slow dialup connection with per-minute charges, in places like motels too many miles from the local telephone office in the middle of South Dakota.

Hi Wes,

Abandon the Win98 path entirely and go for Win2000 (NT derivative).

Buy a Mac? A super-sized big Mac meal-deal maybe. This wormy Apple
has been trading on stale laurels (ripped off from Xerox) for 20 years
while contributing absolutely nothing new technologically for more
than half that period. Making see-thru cases is the lamest step
forward they've offered. I've found nothing more amusing than the
standard snub of "my Mac doesn't crash," and then observe it crash as
frequently as any PC - the Mac form of denial. Apple survives simply
by being the not-Microsoft computer - BFD.

Hi Rich,

Fuse the lead at the battery end. Make sure the lead goes through a
protecting grommet in the firewall (that knife edge will saw through
the insulation pronto - and all the more reason to fuse at the
battery). Use what are called forklift connectors to mate to
equipment (or the distribution panel and use smaller versions of the
same connector to the equipment). Integrate a sub-fuse-panel into
this so that individual feeds are not relying on that one huge fuse.
I actually don't use fuses, I go for the resetable circuit breakers.

You need to know the load current to select a good wire size. For a 500W amp alone, that may be 80A or more...probably at least 100A including the transceiver. Get the amplifier specs before you make the decision.

I doubt 6AWG will be good enough. 6AWG at 0.4 mohm per foot, x 2 wires, x 16feet, x 100A = 1.28V drop in the wires alone. Add more voltage drop for the fuses and battery internal resistance, and things don't look too good. You probably want at least 10AWG for the rigs alone (20-30A fuses), or at least 2AWG when you add the amplifier (100A fuses).

hi Wes.

For now i would suggest you keep your current OS.
Since the XP is giving you so much problems. As you
say ... you dont have a tool anymore but a time
consuming machine.

For long term consideration ... maybe you would like
to use your own OS insted of M$. I meen GNU/Linux.
It is public and when you will feel that your current
pc doesn't give you anymore fast service with M$
products, you could experiment with thousands
pieces of public software that includes radio
software, antenna software, propagation, ect all
publicly accessible on the net. The source code is
open so bugs cannot survive.

There are several companies who are assembling the
free public packages of GNU/Linux and selling them
as easy installation cdroms with books ect ...

But I know you mentionned that your computer is to be
used most of the time not administered so that's
why i'm only suggesting. You would have a cost effective
computer and software that's regulary updated and
free of cost. It's public. It' yours.

Maybe reserve a night of serching and learning on the web for
the distribution of Gnu/Linux that would suit you the
best. I tell you Wes, they're is fantastic software for
the radio-amateurs like us in the public domain.
Very cheap but powerfull in the same phylosophy of hams.

Some place to start http://www.linux.org
http://www.linux.com

http://www.mandrake.com (great for newbies)

http://www.debian.org (use to be managed
by a ham... lots
of software for
us. A bit rough
for the new user
though ...)

http://www.redhat.com (largest market share)

http://www.suse.com (highly stable)

You can even have a dual boot machine. That is M$ Windows
and Gnu/Linux on the same PC.

Bonne chance mon ami.

73

Francois.

My daughter, who designs web pages, found out the only way to
reliably upgrade from Win98 to XP was to re-format her hard
drive, install XP from scratch, and re-install all her software.
She tried for a week to install the XP upgrade over Win98 and
it failed to ever function properly.

Wes,

I remoted my Icom 706 under the back seat and routed the wiring under the floorboard of my Yukon. There was even a metal knock out where I wanted to run the wires up through the floor.

I used some #6 wire from the + and - battery post and installed a circuit breaker near the battery on the + wire.

LOOK BEFORE YOU DRILL! The gas tank is on the driver side and close to the floor.

<riffin-rich@cantspam.me> wrote:

|Hi Wes. 3 months ago, I built a new system--a 2.4GHZ P4 with 1GB RAM
|and twin 120GB drives...even more bells and whistles as it pertains to
|Audigy Platinum sound, 48x readers/writers, etc... I thought it was
|best to install Win XP Pro (the state of the art OS to complement my
|state of the art H/W).
|
|Let me define a problem using a common legacy program, Office 2000 or
|previous. Win XP needs Office XP to run "properly" if you want to
|follow the ideal security model. The point of Win XP Pro was to allow
|an administrator to install the software and create user accounts with
|limited permissions. The limited user accounts would then log on and
|use the system without having full-up sys admin priveleges, thereby
|limiting the damage they could cause if they encountered a virus or if
|a hacker somehow ingressed the system while they were on-line.
|
|Office 2K, like its predecessors, doesn't follow the newest/strongest
|security model of XP-certified software. While Office 2K works great
|as when you're logged on as an administrator, it doesn't work great if
|you log on as a limited user. That's because the Office 2K software
|is trying to write to directories (and the registry) which Win XP has
|locked down. While there are ways to fix this problem so that it can
|work for a limited user, you're ultimately compromising the intent of
|Win XP Pro.
|
|For what it's worth, I have an always-on 4+Mb/sec connection to the
|internet. So, security is important to me...but because I'm not
|running all XP compliant software, I'm actually comprimising security.
|(I do run a h/w firewall, ZoneAlarm, and I check for antivirus updates
|DAILY...).
|
|Also, your slow shut down is based on using legacy hardware and/or
|drivers and/or software. My shutdown was screaming fast...under 5
|secs until I installed my old smartmedia card reader. Now shutdowns
|take nearly 2 mins...but I won't pay for a new one because this one
|works for the limited applications.
|
|Bottom lines: (1) If you're going to use non XP-certified software,
|and you're not terribly concerned about maximizing your security
|model, then you're probably better off using Win 98SE. (2) If you're
|using Win XP and going to use log-on as an administrator all the
|time--you probably don't need Win XP Pro because you're not

|fanatically concerned about enforcing security (my opinion...no flames
|intended...) (3) Do not, repeat, do not rely on the very limited Win
|XP firewall. I suggest disabling it altogether and running Zone Alarm
|(far more comprehensive a solution).
|
|Enough for now. Good luck with your tough decision.

Thanks for all of this. My "old" 98SE was slowing down from bloat and I figured the best way to avoid losing stuff was a second hard drive and a new install. Since I was going to the trouble, I thought XP might be the way to go, however, the learning curve and some of the things you bring up suggest that since 98 was serving my needs before it might be best to stick with it.

73,

Wes

The AEA loop antenna used signal strength and/or
SWR to determine position of antenna setting.
Reading the instruction book for the STEPPIR Antenna
it would appear that the 3 element yagi element lengths
are pre programmed per frequency, which would 'appear'
that they are not optimumised for different heights.
Would the difference of height be of no consequence
compared to preprogrammed figures for front to rear
etc. for all frequencies between 14 and 30Mhz?
The antenna was tested at 40 ft when designed.

Sure- move your antennas away from the house far enough that they don't induce RF onto the house wiring. If you can't do that, looks like you'll have to crank down the wick....maybe a long way down, to QRP.

Hi Dick,

That abomination is in the Win98 family. I used to crow how good the system recover tools were, because I used them every day - even that statement became false (it flat refused to recover to the fresh re-install I performed several days before - that I called on that function that soon is telling).

hi:
thanks for replying to this posting.
I have a MFJ magnetic loop antenna.
I removed the plastic housing and to my surprise the
aluminum loop and variable cap were all covered in whitish
Al oxide.

I would like to remove the Al oxide and then put a protective
clear coat of varnish or lacquer or paint.
1) can anyone recommend an easy way to remove the Al oxide ?
someone suggested a Scotch Brite pad ?
2) what sort of covering is transparent to RF up to 30 MHz, and will
stick to bare aluminum ?

It will still take years to do that. Either way there will be a
considerable time lag.

That doesn't mean the software is "bad". It means the consumer wants
features that are bad for him. Someone will fill that market. You don't
have to use the feature.

I wonder how they get 8 kHz BW out of the thing on 80 meters? I would expect more like 2.5 kHz.

It also won't be very efficient on 80 meters, something in the 1 percent neighborhood.

It's too bad that people will try to squeeze too much out of a good thing.

Should work nicely above 20 meters though.

The scotch bright pad and WD40 works very well just spray the aluminum down with the WD40 and let it set for a few mins the scrub with the scotch bright pad will shine up nicely then wipe down with paper towel to remove WD40 left overs

One other suggestion as to the KIND OF WIRE to use:
Check out arc-welding cable from your local welding
supply. It starts at 4 AWG and goes up (down) from
there. Welding cable is extremely flexible and yet
has an insulation that is resistant to chafing and
high temperatures. It is no more expensive than
the "super cables" car-audio suppliers palm off on
the gullible but is a far superior product. (However,
it's not certified to be "oxygen-free" and doesn't
come with gold-plated connectors installed ;-)).

353. Broken glass insulator. Sob!

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-07 00:35:59 UTC
From: Terry <tsanford@nf.sympatico.ca>
Message-ID: <3DA0D6EF.54956004@nf.sympatico.ca>
Source record: 133493

Sob! (That's as in 'weep', not S.O.B as in "That SOB just .... ")
Although it would be an appropriate epithet in this case!

Had receiving antenna ready to go up and today found that someone must have dropped the nice eight/nine inch transmitting quality clear glass strain insulator (not an egg insulator) and it's cracked in two! Nice 'clean' break as it were, matches perfectly.

May be this is a stupid question; but is there any way, using today's glues, say, that I can rejoin the two broken faces together? Or am I just kidding myself? And it will come apart during the next wind storm?

Beg the indulgence of the group. Any advice pro/con welcomed.
TIA.

Terry in windy eastern Newfoundland Canada.

354. Carolina Cyclone Screwdriver Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-07 00:36:43 UTC
From: Jerry Oxendine <joxendi@bellsouth.net>

Source record: 133492

If you are ready to step up to convenient, high performance HF mobile, then please give me the
chance to provide you that product that will fulfill your needs! And at a price that doesn't break
the bank! You will find in the Carolina Cyclone antennas NO PVC, very heavy duty coils, windings, and power handling that can make your mobile sound like a base! (up to 800+ watts for
Cyclone I). I am retired and I build these antennas as a hobby and a small supplement to my retire-
ment income. There are, I believe, comments on my products on QSL.net. I really try to do a good job. So far, I have had many satisfied customers. If you have problems, I will repair, replace, or provide replacement parts free of charge for 2 years after purchase; I want you to be
happy. The Cyclone I is a FULL 2" diameter and uses #14 wire wound at 8 TPI rather than the
1 1/2" PVC wound with #16 wire at 10 TPI. Price is $240 including shipping to lower 48 states.

Cyclone II is a FULL 3" diameter using the same materials and construction techniques. The size
allows for even higher "Q" and power handling of 1500 watts! Price is $350 including shipping to
the lower 48 states! Compare that with the "BIG" names! Hey, I'm not just a builder, I am a regular user and I get results!!

The weather in the South is getting cooler. Get YOUR Cyclone installed and ready for effortless
QSY and high performance for the colder months!

Welcome to a very large club. Blow out XP and install Win 2000 Pro.
It's basically a $150 worth of NT and it'll run any piece of software
which ever ran in any PC until these goofy XP apps came along. XP
strikes me as some kinda bastardized version of NT server with it's
main objective being to render any current apps you have obsolete and
force you to buy XP-compatible apps from guess-who. And Lord help you
if you try to install a pirated copy of any MS app if you're running
XP. XP is all about maximizing the volume of money in Our Bill's
pocket and nothing else. Been a tough year in his shop, pore
struggling fellow . .

My installation of Norton Anti-Virus 2002 automatically pings the
Symantec server when I log onto the net and completely updates itself
in the background. How much better can virus protection get? Have you
followed the stories about Micosloth's monumental bungling of security
issues??

Yeah, you need a real firewwall, not the lame crapper in XP.

>
> Should I buy a Mac?

Macs do many thing well. What Macs cannot do however is run 99.95% +/-
of the sum total number of apps currently available for use in desktop
'puters. WRT just to ham radio alone none of the rig control apps will
run in a Mac, ditto the mainstream logging programs like DX4WIN, CT or
Writelog, or any of the ham-level antennas modelers like EZNEC or
Nec-Win-Plus. If you happen to be an engineer or scientist Macs are
still farther out of consideration. Great dorm rat's surfing boxes
though, ya can peer thru the cases to watch them work and ya even have
yer choice of colors . .

I will echo what some have already said. If Win98 was working for you,
stick with it. Just because something is new doesn't mean it is better. I
have had limited dealings with XP, and don't have a problem with it (I work
as an IT professional). I have seen Win98 present the same eternal shutdown
you mentioned with your XP machine.

Use what works for you.

I doubt that you can glue it. I would replace it
with a piece of plexiglass. If the wires are soldered
around the insulator holes, just smash the ceramic
apart with a hammer. Irv EX VO1KW (1979) now VE6BP

Hello,

At what elevation angles and azimuths were the field strength test made?
Were all of the antennas tested on the same mount to compensate for
grounding differences? A screwdriver on top of a motor home will probably
knock the pants off a mobile whip mounted on the bumper of a Geo Metro!!!

six gauge aught to do fine, for the extent of current draw, your amp will
draw about 40 amps , yo radio bout
10 amps..a single 100 amp alternator is really all you need (like the ones
in ambulances) dont know what school
the gentleman went to implying the amplifier will draw 80amps, lets
see...500/13.8 isnt near 80, more like 39 amps.
(i use ohms law) expect to pay a pretty penny for the wiring, remember, you
get what you pay for..as for the second battery i recommend a battery
isolator , this thing will fry, boil, stink, leak or all the above..after
all is said, don't use no cheap antenna....

Wes, If you do go back to Win 98, consider backing up your data to the second hard drive, formatting your Win98 hard drive, and starting over...load the Win 98 OS onto a cleanly formatted disk. Then be sure to run all the MS updates/service packs...ensure you've got current antivirus protection and the most current ZoneAlarm firewall...a new release of the firewall came out about a month ago...

Also, I didn't mention that you could also consider running a dual-boot system...but that's another whole can of worms. Good luck with whatever you decide. Take care...

Nope, a typical battery uses 900CCA (Cold Cranking Amps), or around 850 nominal. Take that times 2...1700. He said he has 2 batteries/alternators, probably 100 amps a piece, if it was my 4x4 (my Bronco has a 1000 CCA battery, and a 100 Amp alternator).

I don't remember his brand but my HS-1600 from High Sierra placed
near the top in recent shootouts. I have the three foot RV extension
on the bottom and a large top hat on top.

Of course it matters. The length of the 450 ohm ladder line also matters.
The length of the 450 ohm ladder line plus the feedpoint impedance controls
the impedance seen by the coax which sets the SWR on the coax.

You can see for yourself by downloading the free demo version of EZNEC.

Too bad there are other laws that apply in this case as well, like the class AB power amplifier efficiency law and such. According to these, in order to get about 500W out, your input power must be around 850-1000W, depending on the frequency.

Therefore, the 80A figure is fairly accurate, not to mention that the IC-706 draws 20A in transmit, per manufacturer's specifications.

Apparently, the gentleman in question didn't go the same school you went to.

Tnx, Rich. Last January I bought a new Compaq laptop that had ME installed and which came with the WIN XP Home edition upgrade CD. Based on what I had seen and heard of XP, and the fact that I had some peripherals with no new XP drivers, I instinctively decided not to install the XP upgrade and still have not.

ME is no bargain, in fact it's a real klutz at times, and I think when I finally have to do something radical to get it to work at all- that's coming soon I fear-, I'll just go back to 98 SE.
I bought one of the very last copies of 98 SE (Second Edition) shortly after XP came out. And I note that Leo Laporte of Tech TV (formerly ZDTV) who seems to be about as knowledgeable on operating systems as anyone, once said on his program that 98 SE was the most stable Win OS out there, outside NT. That was nearly a year ago and maybe he's changed his mind by now, but I think I'll stay with 98 SE since it has been shown as one of the more reliable of the Windoze stable, and I have it already.

XP and all the baggage it carries just doesn't appeal to me. I don't need to be tied (chained?) to Microshaft's apron strings, and having to

dial them up and plead for permission to use XP again and again to infinity after every reinstall just doesn't trip my trigger.

BTW, that same laptop seems to eat resources at a prodigious rate nowadays. Even stalls at times because of it, demanding a reboot. Did I pick up a virii or worm that's doing that? Norton was dumb if so.
I had a couple pretty sophisticated memory-hogging games on it for my little grandson to play when he was here visiting, but I uninstalled them but it didn't help (it's 128meg). Still loads the system down after it has been in use awhile. And Norton Antivirus 2002 got balky and went into some kind of a run-forever loop I'd never seen before, so I uninstalled it, intending to reinstall, but now it won't let me. Says something like "System administrator has determined that this install is prohibited" or words to that effect. I'm the 'system administrator' and I did no such thing.
Is it that there are now some very sophisticated virus writers out there, or just the nature of the Windoze beastie(s)? Wats going on? Is it time to bite the bullet and go for a 'format C:\'?

Dick

> neighborhood.

==========

Just visited the site. Very nice photographs.

The write-up has a bafflegab content. Like the CFA it is suggested this very small loop does not work according to conventional theory.

It's easy to get a large bandwidth with such a high loss in the loop. It makes a virtue out of a vice.

The HF loop diameter is 3 feet. Loop conductor is coax braid. The tuning capacitors are ordinary 2-gang receiving types.
Will withstand a few hundred volts rather than a few thousand. Estimated radiating efficiency is unavoidably worse than 0.1 percent on 80m.

Virtues of the ideal radiation pattern will likely be spoiled by radiation from the feedline.

But as always, the German mechanical construction is a joy to behold. Excellent portabilty. Carried on a bicycle. But no miracles can be expected radiowise.

Reg

Source record: 133513

Hi Terry,
I think a pure epoxy glue or epoxy filled with glass powder might cure your problem, unless you are going to use the antenna for QRO. Take care to avoid epoxy filled with metal powder, zinc oxide etc.

>K3PID

YES, it matters-- as a general rule you should keep the coax in such a
setup as short as possible (between the balun and tuner.) and use the
best coax for the purpose you can find . hard line is good. try to
keep it under 10 or so feet. The best way is to run the balanced line
all the way to the tuner.

378. Touch Switch QRM

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-07 12:40:57 UTC
From: Richard Fry <rfry@adams.net>
Message-ID: <vhfo9.11498$34.1321700@newsfeed.slurp.net>
Source record: 133517

Are there any fixes to kill the QRM radiated by a small lamp controlled by a touch switch (other than unplugging it)? I have one that generates noise in the MW/HF bands even when it is off.

379. What gauge for a QRP dipole? Reflector?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-07 12:41:43 UTC
From: cprstn54zz@att.net
Message-ID: <3da17ef4.528396703@news-server.optonline.net>
Source record: 133518

I am putting together a backwoods CW QRP NVIS 40M rig that will run at 3 watts.

The antenna will be a half-wave dipole 20 ft up. If I can't find two trees, it will be an inverted-V with the center up 23 ft on a makeshift pole. What is the lightest gauge wire I can use for my dipole that will perform? Do dipoles become less effective as the gauge goes up? Is efficiency a function of wire surface area?

Some say a slightly longer parasitic wire 20 ft below the dipole (in my case, on the ground) will significantly improve NVIS performance. Does the guage of this reflector wire matter?

Maybe something is getting lost here. The batteries may have 1700 amps capacity,
but the radios will not be drawing 1700 amps. Maybe upwards of 20 amps for the
706, and 4 or 5 times that for the amplifier.

Heh...."ME...the Mistake Edition, soon to be crashing a computer near you."
Stay away from it!

I've switched to Linux (bit of a learning curve) and ended up with a Mac I
bought at Shelby hamfest. FWIW, I LIKE the weird colored thing! Works great
(runs the OS9, not the Unix based X yet, but I may try it) and there IS ham
software out there for both platforms. The 2 ghz Wintel platform that I still
have doesn't really outperform either of the boxes, and it still crashes even
with XP installed (and the Microsoft techs haven't a clue..ran fine w/NT, but
XP doesn't want to play). Sigh...think I'll go play with my radios.....6
meters seems to be opening up....tried for an Argentine station yesterday, but
couldn't get thru the pileup.

For electrical performance of wire antennas, should one prefer multi stranded (and isolated) wire, with a higher surface area , hence lower resistance for the high frequency current, or massive enamelled copper wire, if the cross sections are equal?

And is the answer the same if focus is mechanical strength and ageing/corrosion?

Take a look at http://www.g4fon.co.uk/

I haven't tried it yet myself, but it's on the list of things I need to try...

Hi: The typical 5/8 2 meter mag mount has a base matching coil which is tuned to the design frequency. This may prevent the large frequency QSY that you propose. However, that being said, try a stiff piece of copper wire to see your VSWR. Cheaper than buying a steel whip. Keith, VE3JKC.

Henrik,

Supposedly it does not matter whether it is solid or stranded; although theory would suggest that stranded is better because of skin effects. I use #14 insulated stranded wire. This wire, less insulation, is a bit over 1.8 mm in diameter. The black insulation makes it almost invisible unless you look for it. Blue is good also, but not white and red. What I avoid at all cost is stuff called copperweld; it looks like hell, because it never straightens out. If you are concerned about corrosion, cover any splices with heat shrink tubing. My guess is that stranded wire is less likely to break from wind motion. It will probably stretch more, but I don't know that solid wire would not stretch also.

Now that I've poured the concrete for my tower base, I'm
hoping to erect my tower soonest.

I have some of the original hardware that came with the antenna
and bought some new, as well. The bolts are galvanized
and are marked with a 'P'. Is there a good website that explains
this sort of nomenclature?

I also have some stainless hardware of the same size, the bolts
being marked with 'HHW' or a triangle. Can I mix stainless hardware
with galvanized hardware?

Good quality stainless is inert towards other materials in respect to
corrosion, and you can mix it with other materials, without any adverse
effects.

H.

Stranded wire doesn't have greater surface area. The current flows on
the outside of the whole wire, not the outside of each strand.
Consequently, stranded wire has very nearly the same RF resistance as
solid wire with the same diameter.

I'll let people with more experience comment on the mechanical tradeoffs.

Actually, SpamCop provides two services. One is to identify the source of email and provide spam reporting addresses for both the source and for web sites advertised in the spam. The other is a mail forwarding service which holds mail from sources known to be spammers and forwards the remainder to you.

Like all tools, SpamCop requires a little care and intelligence to use. As David ex-W8EZE reported, some people are too lazy or just don't pay enough attention to use the reporting tool properly. I agree with him that those people shouldn't. Spammers, for example, sometimes include the recipient's email address in the email, or occasionally an innocent party. The user has to actually look at the spam and decide which included email addresses or web site should receive the report and which shouldn't. People who aren't willing or able to put forth this amount of effort or thought shouldn't use the SpamCop reporting feature, just like there are some people who shouldn't use chain saws or drink hot coffee.

I haven't used the mail forwarding service Ian refers to. (I believe it's only part of the paid service, which I do subscribe to.) I do know, however, that it holds all incoming email, so you can view it at your convenience and retrieve any that might have been held appropriately.

I'll personally continue to do whatever I can to make the spammers' lives as difficult as possible. And I hope the effort plays one small part in reducing your spam as well as mine.

I doubt that glue alone will hold in tension. However, how about glue
plus a tiewrap through the holes. That should help keep the glue in
compression. Use a large black tiewrap tensioned as tightly as possible.

Agreed, but the problem here is that when the incompetent do the
equivalent of dropping their chain saws or spilling their hot coffee, it's
others who get cut or burned.

Personaly I find it very encouraging to see somebody else showing
that a small 'loop' can be resonant down to 80 meters.
Actually was working barefoot on the 160 band the other day
on my 'loop' and getting good signal reports. Even a guy named 'doc'
was hearing me fine. Reg, my plate capacitor hasn't arced over yet
and I have inputed a 1 KW so I don't believe 'all is yet known' about
the 'loops' abilities.
I suppose it is possible to get 'good' signal reports
on 160 with less than a watt (1 % efficiency you say) but then I would assume
that the German loop inventor also has done the same.
I think it would be pushing it to describe the loop in the same way
one would describe an E/H considering how many loops are in use today

Another problem with tie wraps (along with most other plastics) is that
they'll deteriorate and weaken from the effect of UV rays.

One reason I recommended the ARRL publications is that, by and large, the information in them is accurate. Too many of those "elementary booklets" and other books, particularly ones oriented toward beginners, contain information that isn't correct. And unfortunately, someone not well acquainted with the basic principles will have difficulty distinguishing the good information from the bad. If you share Reg's aversion to things American, I'm sure that the RSGB equivalents to the ARRL publications contain information of at least equal quality.

Hi,

About waves propagation in the HF spectrum, I have always believed that waves (say the 20m) propagated nearly in straight line (let's speak theoretically), oscillating 1/20 "mega times" per seconds on its path between TX and RX. Its wavelength being of 20 m long, on a distance of 100 m (300') there is 5 wavings.
If it was a direct wave it should arrive to me without the least miss, even if I move 10 m or 100 m away as this wavelenght is rather long versus i.e. Ghz and is quasi insensible to obstacles.

But it seems this far to be the way they propagate in the field... Sometimes I wonder to not be able to listen OM living 100 or 500 km away as I hear without problem others OM living at the same distance in the opposite direction or their correspond living some 100 km away from them.

According a friend OM, this is "normal". A 20m wave for example does not propagate as I stated above. In fact such a wave propagates doing huge "hops", making jumps on the ground or via the ionospheric layers : dong, dong, dong, dong... ;-), a true marsupilami ! I don't remember the length of each jump but this is well above a few hundreds meters if not some km each, whatever the HP frequency.

Do you confirm this mode of propagation of HF waves, doing jumps of several km maybe, even if the wave itself is shorter ? What could explain that we sometimes cannot hear a local station or even a DX ? (I do neither speak about the skip distance - that doesn't seems to be the correct explanation - nor the propragation via the ionospheric layers, wherein I beleive such "hops" could exists too between layers, to confirm).

If it is true what medium or energy "supports" such hops ? How such waves change their propagation mode to jump this way ? A very strange affair that escape me ...

Roy Lewallen wrote:
"Stranded wire doesn`t have more surface area. The current flows on the outside of the whole wire (cable), not the outside of each strand."

Litz wire loses its advantage at frequencies above about 500 KHz. Coils are usually wound of solid wire at higher frequencies. Solid wire is just about as good for high frequency antennas also.

Strength is proportional to cross-section when force is uniformly applied so it should make little difference if the cross-section is in one unit or divided among many strands.

Stiffness is different. It depends on wire diameter, or the depth of a member, as well as the cross-section resisting resisting flexing. That`s why the wide-flanged beam was invented for construction. That`s also one reason tubes are used for tower legs and beam antenna elements.

Crevices tend to hold moisture which can speed deterioration. This is not usually not much of a problem to copper which resists deterioration very well.

Tam,, WB2TT wrote:
"What I avoid at all cost is stuff called Copperweld."

I`ve used many miles of Copperweld of many sizes. The springy coil comes right out of it under enough tension. Copperweld also comes stranded and this has less spring and is easier to work with while retaining the Copperweld advantage which is strength and conductivity. The steel is placed where strength is needed and the copper is placed where conductivity is needed.

As I understand the hardness system used in hardware, that is what it
means. Three hash marks indicated the hardest material, one the least,
two the middle.

If I think about it for a while I'll probably remember the name for it.
:-)

EZNEC demo shows that gauge of wire (12-24) has almost no effect.
This is could believe. It also shows that a reflector wire has no
effect. This I find hard to believe.

Dave:
I recently torched a 1-1/2" steel tube off the outside of an aluminum tube successfully. The thermal conductivity of the aluminum helps. The wet rags suggested also help. HOWEVER, the problem you face is one you may not realize. Usually, when we drill holes to fasten stuff together, slightly oversize holes are drilled. In the case of tower sections, a force fit is necessary instead, or the holes will enlarge themselves from pounding by the bolts as the tower moves, even a guyed one. That's not very clear, if you want, I'll provide more detail. Anyway, as you attempt to remove the old bolts, which were a force fit, and then rusted in place, you will enlarge the holes anyway. To overcome this, you will need to go to the next larger bolt, but not remove enough metal from the legs to weaken them. A dilemma. The inserts were there to provide crush resistance, and a tight fit for the bolts, to address the problem I have described. Consider metric, as there may be a metric size just larger than the present bolts which will produce the necessary fit. Another problem is that you really don't want the bolt to have any threads on the part in the hole, which excludes most of the cheap hardware you find in home stores these days. Good luck.

I am sorry, but you really need to do some study on antennas! First of all,
a so-called "tuner" does
NOT tune an antenna in any way, shape, or form! Yes, it provides a match so
that your transmitter
will not fold back on transmit, but on most frequencies, you STILL have a
mis-matched antenna out
there. I have no doubt that I can use my own screwdriver antenna, both of
us on 100 watts and, not only receive a higher signal report, but talk OVER
you while doubling! A screwdriver is NOT
an "inefficient" antenna by any means for several reasons. 1) a properly
designed screwdriver HF
antenna is easily tuned to absolutely precise frequency each and every time.
2) Because there are
no "wander" leads, jumpered turns, or "tuners" that try to make up for other
deficiencies, the SD puts ALL of its RF into the active part of the antenna
while a jumpered bugcatcher still tries to load
those "shorted" turns--even with the jumper in place, at the very least
creating heat and a corres-ponding loss of coil "Q".

Again, anytime somebody tells me they will beat me in a shootout with a
"tuner", I have to take that challenge! Come see me! LOL!

>from) the NBS design for 2m. I brazed them together out of old conduit and
>ceiling tile wire and then painted them black. They worked great; noticably
>better than a wideband commercial antenna. Good enough for the situation
>that was just out of reach for affordable commercial antennas. Most are
>still in use today.

I built a Yagi for channel 11, by starting with a 15-meter (20 MHz)
design in the ARRL Antenna Handbook software collection and scaling it
down in size by about 10:1. The resulting 6-element Yagi is cut for
operation at around 200 MHz - lowest SWR is about 3 MHz above the
center of the 6 MHz band for this channel.

The beam itself is a 5' piece of 1-by-2 clean fir, waterproofed with
an epoxy coating (several coats of polyurethane varnish would be a
good substitute). Elements are copper-plated-steel welding rod. The
driven element is a folded dipole (approximate drivepoint impedance
300 ohms), with a quarter-wavelength coax balun cut for channel 11
(it's short enough to be folded in half and taped to the top of the
beam). The driven-element, balun, and feedline connections are
soldered, and then waterproofed with silicone sealant.

The feedline from this Yagi is linked to the main antenna feed (a
basic mid-fringe Radio Shack log-periodic) by a Channel Master
"Join-tenna" single-channel combiner from Stark.

The antenna cost me perhaps $10 to make, the Join-tenna was about $15.
The signal quality is exceptionally good - definitely stronger than
the log-periodic antenna delivers.

The main reason to do this was that the Channel 11 transmitter is in
almost the exact opposite direction of most of the other stations in
my area. It was a fun and satisfying project... we can now
watch both Channel 11, and the San Francisco stations simultaneously
on different TV sets, and never need to rotate the main antenna.

Yes but I don't think that different materials have the same strength
just because they have the
same number of marks. I think it only holds true for like material.

Also with steel, the harder it is the more brittle it is and the
easier it will rust.

Stainless is generally harder than galvanized steel but stainless is
not as strong as the galvanized
steel.

A bolt supplier will have all the ratings.

From: David Robbins <k1ttt@arrl.net>
Message-ID: <ant3u209oj@enews4.newsguy.com>
Source record: 133458

well, you may be noticing several different phenomena.

in the closest ranges you first pick up the strong 'sky wave'. this is basically line of sight and is what you use most on those uhf and microwave bands.

then, if the ground were perfectly smooth and the earth like a ball you would notice that the 'ground wave' follows the curvature of the earth for some distance beyond the horizon, slowly getting weaker as you increase the distance. on 20m over average soil this could be 100-200km or so depending on power and antennas used.

beyond the range of the ground wave you are in the 'skip zone' as the skywave travels up to the ionosphere and back down again anywhere from a few hundred km's out to a few thousand km's depending on the ionosphere, frequency, and lots of other stuff... but this isn't what is probably bothering you.

Those are the simple things... now lets get messy.

mountains and ridges that are between you and the transmitter can do two things. They can shadow you from the sky wave, and they can scatter the skywave in different directions... remember this for a minute.

buildings, towers, water towers, power lines, air planes, and any other metallic objects between you and the transmitter can also scatter the skywave in various directions... keep this in mind also.

The ionosphere is not uniform and changes drastically during the day. at times you can get near vertical reflections on some frequencies resulting in a very short hop distance... at other times the signal can skip once then reflect back... and the wave can even make it around the world... or it can be absorbed or refracted out into space and virtually disappear. add this to the above.

Now from where you are you have to add up all the possible sources of signals that may get to your antenna. the sky wave, the ground wave, signals reflected from the ionosphere, signals reflected from mountains, buildings, etc. now take all these different wave sources and start adding them up at your antenna, this is much like taking waves in a bathtub or pool created by a toy boat and watching them reflect around and around... at some places they add up and you get a bigger signal, at other places you get almost no signal. and the distance between big signals and no signals can be a very small distance, in extreme situations as small as 1/2 wavelength change in location can create huge differences in signals. this is commonly seen on 2m repeaters when a user is mobile in a city, on there they commonly call them 'phasing clicks' as the transmitter rapidly goes from strong to

almost no signal. on 2m when you park a car in a lot and talk you can sometimes go from almost no signal to a strong signal by moving your car a few inches... the same is possible on 20m, just the scale is bigger... it usually takes bigger buildings or a mountain to make big shadows and nulls like that.

i hope some of that makes sense, its just off the top of my head trying to explain what can be a very complicated subject without the aid of pictures.

I think you'll find that a reflector wire can have quite an effect, but only under certain conditions. It'll depend on the ground conductivity, the length of the reflector wire (which might need to be considerably shorter than a free space half wavelength if it's close to the ground), the height of the reflector wire above ground, and the spacing between the antenna and reflector wire. Be sure to use the Real, High Accuracy ground model in EZNEC for this analysis.

One possibility is the Anderson PowerPole connectors (the 30-amp
variety), plus a RigRunner distribution panel. You'd get flexibility,
and independent fusing on each individual feed.

Another possibility - take a look in Home Depot, in the area where
they sell circuit-breakers and breaker panels. You'll find some
"grounding bar" devices... rectangular metal bars, with set-screws and
holes that will take wire up to about 6 or 8 gauge. They're normally
used to bond together the (bare) ground wires in Romex or similar
cable, when the wires come to the breaker panel. You could use a pair
of these - one for hot and one for ground - if you figure out a way to
mount the hot bar so that it's well-insulated from the vehicle's
chassis.

>amplifier yet, but I intend to add it to my setup at some point in the
>future and I'd like to use existing wires unless you all don't think
>it's practical...

Mmmph. A 500-watt amp at 12 volts is probably going to be drawing
well in excess of 40 amps at full output. You'll probably want/need a
dedicated high-amperage feed just for the amplifier, in order to keep
the amp-induced voltage drop in the wire from sagging the voltage to
the rig itself. At that sort of amperage, you may need something like
0-gauge electric-welder wire to avoid an unacceptable voltage drop.

At 40 amps, you're not going to have a lot of transmit time before you
flatten your battery... you'll need to have the engine running. You

might want to consider installing an auxiliary deep-cycle battery
right back near the rig/amp, and then running a heavy-gauge feeder to
the main battery or directly to the alternator. This would
reduce/evade some of the voltage-drop-in-the-wire problem, perhaps.

How big is your loop?

As for tuning a small loop down to 80 meters, there isn't any problem,
except efficiency suffers.

I'm really curious about the other params of your loop, maybe you are
doing something differently. I did some quick calculations and a 1 meter
loop (that was my guess at small) looked really inefficient, and had
almost 10 kV at the capacitor, which was pretty big.

I'm no expert at magloops, being in the process of building my first one,
but these are some pretty spetacular claims.

423. Re: Modeling GP with tapered tubular vertical element and wire radials

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-07 23:50:49 UTC
From: "Joe Giacobello, K2XX" <k2xx@swva.net>
Message-ID: <3DA21DD9.8C2419C1@swva.net>
Source record: 133462

Well, guys, I got no responses to my queries, so I am sending this
follow-up to the Antennas Usenet group also.

I went ahead and put up the antenna today. The model was accurate. It
predicted a minimum SWR at 7.12 MHz and it was actually 7.07 as checked
with an MFJ-269 at the bottom of the antenna. So, it appears that the
Leeson corrections aren't necessary for a tapered vertical antenna.
Why?

After thinking it through, I answered my second question, and smaller
segment lengths do indeed result in the penetration of the segments of
the vertical radiator into those of the radials, which explains the
deterioration of the model's reliability (average gain test) with
increasing segmentation.

Apparently, the feed point placement in the model is not critical.

I merely eye-balled the radial angles and they turned out to be
guestimates at best. Apparently, based on the agreement with the model,
my eye was close enough.

If anyone has any comments, I'd be interested in hearing them.

You need to check out some of the CB shoot out sites. They have cars with 8 or more alternators turned by big block NOS injected engines. If you have less than 10,000 watts output, stay home.

The size of the wire does not mater to the RF. The only thing is how big it must be to support itself and any ice that may form on it. I doube that a wire layed on the ground would help but if you put a wire slightly longer than the dipole about .1 to .25 wavelengths under the antenna it will shoot much of the signal up and should lay down a beter signal for short ranges and not as much for the longer ranges.

The NEC-2 error caused by tapering is quite small. It's small enough
that you can usually ignore it when modeling a dipole or monopole. Where
a small error has a relatively big effect is when it's in a parasitic
element. There, very accurate results are necessary in order to get an
accurate radiation pattern, particularly an accurate front/back ratio.

The correction doesn't require equal length tubing sections, and I don't know what you mean by "non-linear". The requirements for EZNEC applying the correction are that the element has to be straight and within about 15% of self-resonance (quarter wave resonance for a monopole, half wave resonance for a dipole). It also can't have any sources, loads, or transmission lines except at the base of a monople or center of a dipole. "Show Stepped Dia Correction" in the Wires Window "Other" menu will show you if a given "group" (series of connected wires -- an element) is being corrected and, if not, why not. More detailed information can be found in the EZNEC manual under Building The Model/Modeling The Antenna Structure/Advanced Wire Features/Stepped Diameter Correction.

>>Nevertheless, when I run the average gain test on the as-is model, I
>>get
>>a very respectable 1.017, strongly suggesting that the model is valid.

A good average gain test doesn't mean that the correction is needed or not. It only indicates that the total radiated power equals the total power applied by the sources. The NEC-2 error occurring when wires of different diameters are connected only affects the reported impedance (reactance, mainly) but not the ratio reported as Average Gain.

>>It also turns out that the average gain test value deteriorates as one

>>penetration of the lowest tubing segment into the adjacent segments of
>>
>>the attached radials.

This is definitely a possible cause of deteriorating Average Gain. Also, unlike MININEC, there are situations in NEC-2 where longer segments are better. The vicinity of a stepped diameter junction is one of them.

>>My questions are:
>>
>>1. Given the satisfactory result from the average gain test, is the

Probably not, if the antenna is around a quarter wavelength high. If it's close to a half wavelength, the sensitivity to the feed point position becomes a lot greater (and I wouldn't trust modeling results to be very exact). Move the source up a segment and see how much change you see.

>>4. From a practical standpoint, the feed point impedance of the

>>Are there tools available to make this measurement?

If a few degrees makes that big a difference, I wouldn't spend a lot of time getting the angle precise and expect the impedance to be exactly what EZNEC predicts. Factors EZNEC doesn't know about, like wire sag and other nearby objects, are likely to skew results anyway. If it's that critical, watch the feedpoint impedance as you adjust the radial angle, and stop when you have the impedance you want.

http://www.americanfastener.com/techref/grade.htm

Rohn hardware is grade 5 and you shouldn't use lesser quality.
|
|I also have some stainless hardware of the same size, the bolts
|being marked with 'HHW' or a triangle. Can I mix stainless hardware
|with galvanized hardware?

Yes. One caution with stainless steel fasteners is that you should
lubricate all threads to prevent galling. Generally, I would stick to
grade 5 galvanized unless there is a dissimilar metals problem.

I have no interest in "Cold cranking AMPS" I am talking about sheer AMP Hours here. For that kind of current without much voltage drop you would need something on the order of 6 ought wire to deliver that kind of current. You go ahead and try pulling 1600 AMPS from your two batteries, I bet in very short order you buckle the plates in all the cells. Car batteries are NOT designed for continuous high current draw, only short bursts such as starting. That's what DEEP cycle batteries are for.....SUSTAINED draw of current.

Richard,

I will have to admit I never actually used copperweld. I was going by observation of what a couple of friends dipoles look like - wavy. BTW, didn't know about the stranded copperweld, but once had some WW2 military field telephone wire that had both copper and steel strands.

Roy mentioned corrosion, I was surprised to see that even insulated wire gets some surface corrosion after a few years.

I have a 75 meter full size vertical loop, made of cheap Carol #14 stranded wire that has been up for about 5 years now, still going strong. That's about 250 feet of wire up in the trees (BIG trees). In case anybody is interested, the top wire is at 75 feet, the longer bottom wire is at 20 ft. Feed is at one corner. 1/4 wavelrngth of RG11 gives me a good match to 50 ohms.

Tam/WB2TT

Roy,

Why is the reflector on the ground? I ran EZNEC on a 75 meter antenna with a wire reflector at 50 feet, resonant lower than the antenna, and got something like 3db added gain for a spacing of about 30 feet. Never built it, because the tribander would get in the way.

That's the reason for using the black nylon ties. They're made to be UV resistant and the larger ones are used commercially to tie coax feedlines to tower legs. They last a long time, I have some that have been up for several years. Some even use a metal insert for the locking catchpin.

The white nylon ties I previously used would disintegrate in a few months.

I once designed an omnidirectional 40m antenna that EZNEC said had a
22dBi gain. :-)

Some hams straighten Copperweld by tieing one end of a length of it to a tree, the other end to a vehicle bumper, and "stretching" it just slightly.
I was always a bit leery of this thinking that it could break and whiplash with potentially disastrous results.

If you cut it down to marine frequency what are you going to use it for?
If you put it on a boat it will have to be steel for the magnet to
stick and will not work too good without a ground plane. The mag mount
is designed to be capacitivly coupled to the ground through the base.

I use heavy duty jumper cable wire for just my rig. It's probably #6,
but I'm not sure. It's real thick stranded wire with thick insulation.
I have to remove strands to fit it into the anderson connector pins. I
snipped it from a set of old jumper cables that had bad clips on them.
But this wire is not to be confused with the thin wire you get from
the cheapy cable sets at walgreens, etc. That stuff is thin. Myself, I
don't recommend running the same wire for both the amp and the radio.
I would want seperate wires for the rig and amp. The way I see it, the
rig itself will have a more stable voltage if it's not on the same
wiring as the amp, which really draws some current on voice peaks. Not
to mention the wire would need to be really thick to run both without
problems. The battery/s itself can dish out some pretty hefty current
without a huge voltage drop. But factor in wire resistance, and high
current draw, and I bet you could see some pretty large swings in
voltage with both on the same line. In a worst case scenario with
marginal wire, you could "FM" when on ssb, or chirp on CW. If the rig
had it's own thick wiring with no other large loads on it, I'd think
it would be more stable. Also, I agree with one, if you plan on
running an amp, plan on large current being available. Don't micky
mouse around in that dept or you will have problems for sure. I'd plan
on 80 amps minimum for any kind of 500w amp. Even if you don't

actually draw that much current on average, you need the capability on voice peaks. Too thin a wire, and the voltage drop will eat your lunch. Also, I use the anderson power connectors. They seem much better than anything at a store. IE: radio shack, etc. I've never had voltage drop/resistance problems with an anderson connector.
I sure have with molex plugs though...Fuses and fuse holders can be a problem after a while also. I remove them and clean and replace every so often. If you can wiggle the fuse holder and see your power output fluctuate, you probably have some resistance and need to clean it out and make sure the holder fits the fuse tightly. Also as a parting shot about wire overkill, remember that what works fine with the engine running at 14-15 volts might have problems after running a while with the engine is off and the voltage starts to drop. The larger the wire you have, the longer "talk time" you have before you reach the critical low voltage point at the rig. Icoms can be picky about this. I've heard many of them chirp and FM when used with thin wire.
It's usually someone that is out camping or rv'ing and using a battery. And probably too thin a wire...I've never had a stability problem with the thick stuff I use running a 730 or a 706. The 730 didn't really care for low voltage too much as far as keeping stable. The 706 will cycle off and on if the voltage drops too far. IE: same as when you start the car and you see the radio recycle itself...But thats a worst case...You would need horrible wiring to have that happen. I've never tested it to see how low a voltage it can run at and be stable yet. I do know it's a current pig. The thing draws nearly 2 amps just on receive if all the lights, etc are on. Will sap a battery down a bit just sitting listening for a while. MK

As far as I know, it wouldn't matter. IE: a NBS yagi at 40 ft has the
max gain of that boom length/element spacing. At 10 ft, it will still
have the max gain for that boom length/element spacing. The only thing
that changes is the effect of the ground on the pattern. IE: usually
higher angles at lower heights in general. MK

They differ thats for sure. There is one brand in particular that is
pathetic.
The coil has so much loss, it's a wonder it works at all. And the
worst part is , the guy seems to design them that way on purpose. He
says they give a "good match", or something along those lines...The
antenna a friend of mine bought from him was so low Q, I has trouble
finding the noise peak when adjusting the coil. Really bad news..No
decent mobile antenna can operate without impedance matching. If it
does, look out for excess losses. On the other hand, many are decent
antennas, and comparable to a bugcatcher. Just depends who, and how
they build them. The better ones look kind of like adjustable
bugcatchers. Big fat low loss coils. MK

The stranded wire actually has more loss than solid wire of the same diameter. If used for the center of coax it is only a few tenths of a DB at vhf. For a antenna tha additional loss is so low that it doesn't make any differance.

Henrik,
as others have pointed out there is very little if any difference in performance in strandard vs. solid wire
antennas at HF. The one consideration that is important is actual strength. I've have very good sucess with
cheap #14 Stranded Thnn wire here. Use it for my 160M Loop (520') horizontal loop. works great been up 4 years
now.. It will not do well in heavy Ice , for that I'd used copperweld. But for most HF antennas it works
great. I've personally have problems with the enamalled solid wire , it breaks after a few years of flexing in
the wind. (But I use trees for support) if you have a pole or tower then the problem with solid wire might
not be as bad.) My rule of thumb is that if using solid copper wire I go up to sizes in guage.
Just my two cents worth..

Hello Thierry,

The easiest and more practical way is the piece of electric wire! It's unexpensive and if you have two ones of approximatively 10 meters each, you can step in for a dipole, Marconi, Levy with a coupler and ladder line, folded dipole, rhombic or loop antennas.
For field action you just have to add a fiberglas pole.
And tht's it, the perfect travel setup.

Hi,

Well, I just passed my Foundation Licence Amateur Radio exam. I'm taking the RAE Full Class A in December (my morse is now up to speed), but did the Foundation as a means of getting on the air sooner.......

My main interest in this hobby is in antenna design (having done a little of this when I was a kid playing around with 49mhz walkie talkies (of about 25mw!) and trying to get a range of more than 10 feet line of sight!

I'm particularly interested now in helical antenna design, and possibly in the application of that within standard dipole design. I live in a flat where there's no way I could put up a G5RV in the garden.......

So, small is indeed beautiful as far as I'm concerned.

I'd be really grateful if anyone on here could point me in the direction of some good resources (either in old fashioned book form or on the internet) for helical design. Also if anyone has tried building a dipole using helical rather than straight elements, I'd be interested to hear from you. I may also try out one of those Isotron antennas I've read a little about - anyone here using one?

In the meantime, hope to catch some of you on the air for a first contact!

Dean
M3DPE (on the air in a couple of weeks when I'm rigged up!)

There is a wealth of experience with helical mobile antennas. They are
not as efficient as bugcatchers or screwdrivers. The same principles
apply to a dipole. For efficiency, high-Q loading coils and large capacitive
end hats are the way to configure shortened dipoles.

Thanks to help from W7EL with EZNEC, I corrected the ground type and
went to split feeds for greater accuracy. My results are nevertheless
interesting.

For a horizontal dipole, optimum NVIS on 40M seems to occur with the
dipole 20 ft up and the reflector on the ground and 6" longer than the
dipole. This was expected.

For the inverted-V dipole, I found that the best practical result was:

Center 23 ft up. (= 20 ft roach pole plus a little PVC pipe)
Ends 11.5 ft up.
Reflector center 11.5 ft up.
Reflector ends on the ground.
Reflector 4 ft longer than the dipole.

The gain of this inverted-V dipole was only around 0.2 dB lower than
the horizontal one.

From: RMO <rmo7@bellsouth.net>
Message-ID: <soBo9.34619$S8.700528@twister.tampabay.rr.com>
Source record: 133397

I have a 1 acre lot that is mostly tall trees and I wanted to know how bad it is going to be if I get back into radio. I do have about a 40 x 30 area out back that is clear but on the border of this area is the house and tall trees about 40 feet high. Probably start with a dipole, eventually an hf vertical but there again the house is embedded in the trees so its tough to find a good spot to mount a pole that is not next to tree branches.

Let me know what you think about a dipole in the clear but bordered area, will it be ok or will it really dampen my operating?

Thanks!
Richard

Mike, my loop is used in combination with another radiator (a dipole)
where it is tuned to resonate the combination. The archives have a lot
on combination loop/dipoles, but to be honest claims are viewed by
many as similar to those made for E/H antennas.

Tam, WB2TT wrote:
"---once had some WW2 military field telephone wire that had both copper and steel strands."

That was tough stuff.

Wire antenna requirements are often similar to aerial open-wire phone lines. Winds of 8-12 pounds per square foot (60-70 mph) with 1/4-1/2 inch ice loading may be anticipated at temperatures of 0 degrees F, for example. Spans between phone poles is often 150-200 feet.

Copper wires have a breaking strength compared with Copperweld:
#12 320 lbs. 750 lbs.
#14 200 lbs. 500 lbs. (0.064 inch)
#16 130 lbs. 310 lbs.
#18 80 lbs. 190 lbs. (0.040 inch)
#20 50 lbs. 120 lbs.

Wires are often pretensioned to about 10% of breaking strencth. Sag can be determined from temperature and tension in the wire. If appearance and accidental contact aren`t issues, some sag is usually unimportant.

The Signal Corps had at least 3 varieties of roll-out telephone pair wire, "assault wire", "field wire", and "tactical wire". Your phone company uses permanent "tactical wire". Each variety at times came in various lengths, wire compositions, and insulations.

I bought surplus, at the end of WW-2, a DR-5 reel of W-110-B (Field wire). This was one mile (5,280 feet) 154 pounds on the reel or 120 pounds minus the reel. It was twisted pair, each conductor was rubber and braid covered and composed of three 0,0135-inch copper strands and four 0.013-inch steel strands.

The Signal Corps advised not to load this field wire in excess of 40% of its breaking strength of 300 pounds. Limit on some other wires was 30%.

I found a lot of uses for this wire.

Best regards, Richard Harrison, KB5WZI

well with all those trees i would put up full wave loops for what ever band you
wish to work on
the only bands your going to have a real problem with are VHF and above and if
you really wanted yagis
but hey nothing is forever you could always cut a couple of the trees down
that are near the house and then put up a BIG tower to get over the tops of the
trees and then you can put up what ever you want
but for HF trees are your friends cause you can string wires from them and the
leaves dont block any of the RF
good luck

I'm thinking of building one of these antennas. My plan is to use the all coax approach. 125ft of RG59 going vertical about 40-50 ft and the rest horz. Then lay down about 10-15 or so 63ft ground radials. I plan on feeding this with some LMR400. Does anyone see a problem with this configuration? Also is there anyone using this type of setup? Any Pro/Cons?

Thanks

Richard,
I wish I had your problem! Mine is just the opposite,
not enough tall trees to hang antennas from. While an
antenna should be 'in the clear', it certainly isn't an
absolute necessity, and antennas running through the trees
should work just fine for you. Sure, the trees will affect
the antenna to some extent, but not enough to really be
noticable on Hf. If the trees are close enough that there's
no way to get an antenna up, they're too close and should be
'thinned out' anyway. Put up an antenna and have fun...

Hi Dave,

Before you have to cut or torch, find a ham that has an air compressor, a large one with an impact hammer gun and the proper tips (or rent one).

You should be able to force the broken bolts out of the leg with the impact from

the hammer gun.

If you need to cut and drill, get some help to bring the drill press outside so you
can work safe and in the light.

73 guy

Source record: 133407

Henrik,
It makes very little difference whether you use stranded
or single conductor wire. The primary difference on HF is
mechanical. There are some differences, though, which deal
primarily with where you live and the amount of 'stuff' in
the air (polution). Bare stranded wire tends to corrode and
the movement of the strands of the wire can produce noise
because of the differences between how much each strand does
corrode. In areas that have a large amount of polutants this
is more noticable than in areas that are less poluted. The
'cure' for this is to simply use insulated wire and seal the
ends that have to be bare. Also, this corrosion 'noise' isn't
a big problem to start with, but it is there.
Mechanically, stranded wire tends to be easier to work with.
It tends to 'kink' less, and is easier to bend.The biggest
difference, at least in the area where I live, is in cost. The
stranded wire seems to be less expensive depending on size.
So, the 'best' type of wire for HF use is whatever you happen
to have the most of, that's strong enough to support it's self.

"Dean Elwood" wrote
> I'm particularly interested now in helical antenna design, and possibly in
> the application of that within standard dipole design.

==========

A helical antenna, very short in terms of a wavelength, is one where the loading coil is elongated to cover much of the length of the antenna. The inductance of a helical loading coil, length, diameter, number of turns, etc., is exactly that which resonates a very short vertical antenna to behave similarly to a full size 1/4-wave vertical - except that it is much less efficient. For a vertical a good ground connection, such as a number of shallow-buried radial wires, is needed.

For analysis af performance of short, simple, helically-wound, vertical antennas download in a few seconds program HELICAL3 from website below. Run immediately. No unzipping inconvenience. The helix can be capacitance loaded with a rod.

Two 1/4-wave verticals connected-back-to-back behave as a short, horizontal, half-wave resonant antenna. This has the advantage of zero ground connection loss.

For design and analysis of performance of centre or helically-loaded horizontal dipoles download program MIDLOAD from website below. The antenna ends can be loaded with rods or wires to change frequency.

==========

> I live in a flat
> where there's no way I could put up a G5RV.

==========

Don't worry, there's nothing lost. The G5RV with its supposedly critical dimensions and extra length of lossy coax, wherever space can be found to erect it, taking one band with another, is always less efficient than any ordinary, random length, similar size diople. But not a lot ;o).

I have a bunch of 80-100 foot oak and tulip trees on the property. The tribander and 6 and 2 mbeams are at about 40 -46 feet. The trees do not seem to cause a problem. I would not worry about them below 430 MHz. Had to have 1 tree taken down so I could rotate the tribander. On the other hand they allow the 75 m antenna to top out at 75 feet.

Ken,
The size of the wire should be large enough so that it will support it's own weigth plus whatever ice, etc, may form on it. For HF purposes, if the wire ~will~ support it's own weight, there will probably be very little advantage in using larger wire.
Another wire placed under the dipole will make a difference in the radiation pattern of the antenna. So will having a very good ground system (basically the same thing, sort of), and varying the height of the antenna. How much difference will it make? I don't think anyone can tell you that (including those using antenna modeling programs), so try it. See for your self. I can say that there isn't going to be anything close to 20 dbi of difference!(LOL)

WF3H,
Yes, you can cut the antenna for use in the 150 Mhz
area. How much you will have to shorten the antenna
depends on the impedance matching device at the base
of the antenna, though. Trim it in very small 'chunks'
while watching the SWR. It'll be easy to go too far,
so take your time.

Dave,

That seems like a good summary of what most people agree with. To keep the wire from, breaking in a windstorm, I found the following works: Fasten down one end of the support wire (rope) only. I tie the end of the other one to a cement block, resting on the ground some distance from the tree branch that it goes over. When the trees move, the cement block will move closer to the tree, giving more slack. Note that there is not a continuous motion like you would get with a pully. In the worst case, you have to put the cement block where it belongs once or twice a year. The best material I have found for the end "wires" is black Dacron rope. Also, plastic cowered clothes line is much superior to some kinds of rope, which will rot in a few months. As for ice, clearly the problem gets worse the longer the span. Probably a NOP at 20 meters and hugher.

Some X-ray tubes use metallic beryllium for the windows, low atomic
weight means it's transparent at quite low energies. They come
with a similar warning. Be careful, the toxicity is dangerous,
over and above any carcinogenic risk. Even Be/Cu alloys should
be treated with caution - no grinding and cut under water.

> I'd be grateful if you could point me in the right direction for finding
> that wealth of information!!

I'm not sure that wealth of *experience* is written down anywhere. It stands to reason that the highest-Q coils have the least losses. The Q of a helical-wound HF antenna is pretty low compared to a bugcatcher coil, for instance.

75m mobile antennas are a study in performance Vs length. Virtually everything is known about them. High-Q center-loaded coils and very large top hats win the 75m mobile shootouts virtually every time.

Decide how long your dipole can be. Decide how big your end hats can be. In the center of each leg, install the highest-Q coil with the lowest amount of inductance that it takes to bring the dipole to resonance. That's just about as efficient as a shortened dipole can be.

Hi,

This mail and others I received in my private mailbox confirmed the "basic propagation notions" I knew and publsihed on my website, that HF waves propagated via the ionosphere layers what explains this skip distances for nearby stations. I knew all you stated and I prefer your explanation to my divagations, based probably on partly misunderstood of my problem by my friend when I questionned him, and my bad interpretation of his answer.

Hi,
I need help in feeding methods for notch antenna. I built a
notch for 2.4 and 5.78GHz and facing trouble in feeding it. Is coax
feed used for notch or microstrip line as in slot.Kindly explain.

Thanks in advance.

486. Best noise canceller : MFJ or Timewave ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-08 18:52:47 UTC
From: Thierry Lombry <lombryt@hotmail.com>
Message-ID: <3da32960_2@news.vo.lu>
Source record: 133325

Hi,

I would like to buy a noise canceler for a friend as a gift to help in suppressing some directional nosies. I use several time the MFJ-1026 but I don't know the Timewave ANC-4 (ex-JPS) that looks more modern . Both devices works exactely the same way (cancelling noises in phase opposition using a 2d antenna) and prices are nearly similar ($180-210). Only problem there is maybe no dealer for Timewave in Europe, so i suspect their proeuct to be about 25% more expensive.

Has someone already made a test of both devices and find one better than the other to remove RFI (QRM) ?

NB. As I don't know the Timewave yet I'am of course more attracted by it, but is a good idea.

Thanks for comments

Thierry

> (I use plastic to prevent rust).

I have one that I modified to use the Yaesu ATAS-100 "mini screwdriver" antenna, and it works very well. It's designed for Hamsticks, and the ATAS-100 is well beyond the manufacturer's ratings, but I've had no problems.

I would NOT use plastic/nylon screws with this mount. The forces put on the screws by the wind would probably break them, or pull them out in short order. Also, make sure that the screws are going into a metal fastener, and not nylon inserts. My car (a Camry S/W) has nuts welded to the metal inside the hatch, so it works fine for me. If it had nylon inserts, I would have probably popped them out, and used a drilled/tapped piece of bar stock on the inside of the sheet metal.

Another reason to use metal screws is that it grounds the mount.

Someone else questioned the use of this mount with a halo/squalo. It would work just fine. Use a piece of 3/8-24 all-thread in the mount (don't connect the coax to the mount!), and use a couple of nuts at the top end. There are masts made for this; I think M2 makes (made?) them for their HO Loops. And as for VHF/UHF verticals, they work just fine on this mount, as long as they are fairly long (get a bit of metal up in the clear). A bumper mount 1/4 wave 2m antenna just isn't going to cut it.

Actually, NEC does quite well with most close spaced and tightly coupled elements, provided that you make sure the segment junctions are aligned if the wires are parallel or nearly parallel. It's MININEC that has the most trouble with closely spaced wires. The original MININEC3 would pretty much come unglued if the wires got too close, but there's a simple code change that can fix this. (See "MININEC: The Other Edge of the Sword", _QST_, Feb. 1991.) But even when fixed, the segment length in a MININEC model should never exceed about twice the wire spacing. NEC and NEC-based programs like EZNEC can get by with considerably sparser segmentation provided the segment junctions are aligned.

An NEC-2 analysis of a beam with tapered elements will almost certainly show a pretty badly inaccurate front/back ratio. If you want good results, you'll have to calculate and enter the constant-diameter equivalent. A method for doing this is given in Leeson, _Physical Design of Yagi Antennas_. NEC-2 based programs like EZNEC use this method.

Richard, KD4UWV wrote:
"Let me know what you think about a dipole in the clear but bordered area, will it be ok or will it really dampen my operating?"

"Electrical Communication Systems Engineering" was commissioned by the War Department in 1945. Leading experts were collected to produce it for , according to General George Marshall, "the information and guidance of all concerned". It is encyclopedic.

Excerpts:
"the best locatiion for a rhombic antenna (ditto for a dipole) is over flat, level terrain with no obstructions beneath or surrounding an antenna. ---Isolated trees within the rhombic area will have negligible effect on the performance of the antenna. However, the antenna should not be erected over a heavily wooded area where the trees are an appreciable height compared to the rhombic.

For a horizontal antennas over the earth, the required take-off angle for the sky wave is the same as the angle in the reverse direction back to the antenna. The reflection point should be clear of obstructions. This is simple geometry and graphics.

Art Unwin, KB9MZ wrote:
"---my loop is used in combination with another radiator (a dipole)
where it is tuned to resonate the combination."

Ed Laport in "Radio Antenna Engineering" on page 105 wrote:
"The quarter-wave shunt-fed radiator is the unbalanced analogy to the
delta feed so commonly used for horizontal dipoles at high frequencies.
In the latter system, the shunt feed is balanced. In both cases, the
transforming action of the shunt feed is relatively small, and the
reactance itroduced by the feed wire is not excessive, giving input
impedance of relative high power factor. Furthermore, the feed loop is
not sufficiently large to cause excessive radiation, though there is
some.---In broadcast applicatiobs, radiation from the feed loop causes
the vertical radiation pattern for the single radiator to be distorted
and eliminate the cone of silence directly above the radiator."

In a dipole, the nulls at the ends of the dipole might similarly be
eliminated by a loop imposed on its feedpoint. This could be desirable
in some applications.

There's an inverted-L constructed with the outer conductor (the braid) of a coaxial cable. There's the usual vertical and a horizontal sections. And then there's some ground radials.

What I would like to know, please, and so are a lot of other anxious readers, is where are the two feedline wires, presumably coax, or tuner, connected to the antenna.

Where does the inner conductor of the antenna coax come into it ?

Is it left floating, not connected to anything ?

Very few people are mind-readers. < big grin >

Source record: 133344

Hi everybody,

I have a 3 el. Yagi (Hy-Gain) that I want to use for 10-meters as well as CB. I currently run a 40-meter dipole through a tuner and it works really well for 10 through 40, including CB. (End-fires like a flame-thrower.)

My question is...is it better to tune the Yagi to be resonant on 28.444 MHz and use the tuner for 27.405 MHz, or the other way around? I still chat with my father on the CB ch. 40 USB and while adequate, he's still approx. 60 mi. away. I notice that tuning for 27.405 MHz puts a little more aluminum in the air. (Albeit just a few inches worth.) I just wasn't sure if it made any difference. Thanks in advance.

Richard,

I've had antennas in trees for a good portion of my ham career. I operate mainly 40 and 80 meters. I've been perfectly happy with the performance although I prefer stateside QSOs over DX (can't seem to get them to QSL, hi). I'd say go ahead and give it a try.

73s,

Evan

Well, I am not an expert on RF theory and design! But reading through the papers on PolyPhaser's web site regarding ground systems and studying ground systems in general I've learned that standard practice is to use solid conductor for the ground run. They claim that stranded conductor has a higher impedance at RF than a solid conductor. I suspect they may be considering worst case when the stranded conductor oxidizes and the strands become electically distinct compounded with the lay (twist) of the cable strands. My ground system uses a short length of 1.5" wide copper strip.

Furthermore, isn't there a cite from the electic code that wire antenna be constructed of solid conductor... or some such wording to the effect?

I have some real insight that others may not have to pass along to you. I operate almost exclusively 40 and 80 meter CW using 4 square vertical arrays for each band. These are all right in the tree arena as my entire property is covered with all kinds of trees. No escape and I'm not at all interested in cutting down any of these trees.

The trees are taller than the 40 meter array and many of them are taller than the 80 meter array but at a bit of distance from it.

The 80 meter array does not change tuning characteristics when the seasons change.

On the other hand, when the seasons change and the sap rises in the Oaks, or winter hits and the leaves come off and the sap declines, I guarantee you that the tuning of the entire 40 meter array changes! You can actually see the SWR pattern from direction to direction change in it vary from one part of the year to the other. The effect is minimal on 40, but it is there. The effect on performance isn't noticeable on 40 as far as I can tell, for the forward throw. Gain is relatively easy to get in these arrays relative to tuning and adjustment work, per my experience.

On the other hand, you'll see more noticeable distortion in the Front to Back ratio as the seasons change.

I can tell you that a 20 meter VERTICAL array will have even more sensitivity to tree problems, and so on up the frequency scale, in VERTICAL mode. Because the 'element-like' branches of most trees are not oriented in the same plane and in the same perspective as most horizontal arrays, you'll see less of this for horizontal antennas. For 20-15-10 meters, do whatever you can to clear

the antenna up above and away from the tree game. It's just the shorter and more interfering elemental characteristics of the branches which are hittint you, as opposed to the definite vertical mode model for the trunks!

At the extreme end of the scale is issues like the de-sensitizing of pagers and cell phones in the middle of huge collections of pine needles on pine trees. Here, if and because the needles are right there in the proper elelment length as the object frequencies of these and similar devices, you'll often see devices like these go way down in performance when pine trees are involved. Much more absorption of the needed energy in them.

Now, was this more like what you want to know from a practical standpoint?

Hi,

I have found interesting reviews of both devices on eham of course :
http://www.eham.net/reviews/detail/1138

Hear the effect of the Timewave on QRM (check right to the 5th
picture) : http://www.owdjim.gen.nz/chris/radio/shack.html

MFJ and Timewave :
(not a true comparison but directions)
http://www.hard-core-dx.com/nordicdx/antenna/special/
http://members.aol.com/MarkWA1ION/phased_arrays.htm

About Timewave on 50 Mhz :
http://www.qsl.net/i0jx/anc-4.pdf

Advice to modify the MFJ:
http://www.amrad.org/pipermail/tacos/1998/000283.html
or http://www.angelfire.com/mb/amandx/mfj1026.html

Original reviews in QST:
JPS Communications; ANC-4 Antenna Noise Canceller; Feb 1996
MFJ; MFJ-1026 Deluxe Noise Canceling Signal Enhancer; Apr 1998

Even if users seems to say the Timewave works fine, some consider it
is too touchy, most consider that the MFJ give better nulling of QRM.
This last comes also with an attenuator function not available on
Timewave model.

At last, the price, -25/30% cheaper for the MFJ.

Thierry

Don't bet on it. With the antenna on the barn roof more than 60 feet
away, I could consistently key the touch lamp with 100W of RF. Ferrite
chokes made no noticeable difference in this case. The circuit's RF
impedance seems to be too high for that approach. The final solution
was to open up the lamp and remove the touch switch module.

Radioguy wrote:
"---isn`t there a cite from the electric code---?

Yes.

"N.E.C. requirements:
2591. Material. The material for the grounding conductors shall be as follows:
a. For System or Common Grounding Conductor. The grounding conductor of a wiring system shall be of copper or other corrosion resistant material. The conductor may be solid or stranded, insulated or bare.
----."

Since stranded wire is OK for grounding, it`s OK for any wiring if its physical properties are suitable. As I seem to remember, the power company here insists that exposed aluminum grounding conductors be insulated for protection against accidents and the elements but bare copper is OK with them. I checked the meter service ground on my house. It`s stranded copper of a very large size, >>#6 AWG. I don`t have a handy wire gauge.

Best regards, Richard Harrison, KB5WZI

Steve, N4LQ wrote:
"The author claimed 20+ db gain for local stations---."

With reflecting elements formed into a parabolic reflector?

A folded dipole optimally placed above a very good flat reflector only gives about 5 dbd gain or about 7 dbi gain according to Arnold B. Bailey in "TV and Other Receiving Antennas" on page 523.

The reason is a perfect flat reflection can almost double the voltage of a signal traveling away perpendicular to the reflector and emanating from the dipole and its reflector. Doubling the voltage quadruples the effective radiated power in the best direction so there is almost a 6 db gain. Call it 5 dbd because it`s not quite perfect.

Best regards, Richard Harrison, KB5WZI

I don't think so.
The MFJ has a built-in attenuator not available on the Timewave.
And more I read reviews about both devices more I suspect the MFJ to
work better and to be "easier" to use (not as touchy as the TW.).

This is maybe a good thing as it is cheaper and MFJ has dealers
worldwide.
My first selection was thus probably the good one.

But I should appreciate to read more comments about OM who compared in
the field both devices.

Art Unwin, KB9MZ wrote:
"Hopefully, I will be able to get my hands on that book---."

Art is plenty smart and resourceful too. All Ed Laport was implying, I think, is what I had posted in the earlier thread regarding Art`s clever matching arrangement. The loop is sensitive in its plane and has nulls broadside. When attached to the dipole as Art has done, the loop`s nulls are in the principal lobe direction of the dipole and don`t help. On the other hand, the loop`s lobes are directed at the ends of the dipole where its nulls normally occur. If it is advantageous to fill in the antenna`s nulls (maybe you would like to have a mostly non-directional antenna) the loop placed parallel to the straight radiator may be just what you are looking for.

The loop might be of some assistance to the dipole were it horizontal instead of vertical. It would still fill the nulls at the ends of the dipole, but some of its radiation would be fore and aft instead of up and down where it is of little use.

Best regards, Richard Harrison, KB5WZI

523. Re: What gauge for a QRP dipole? Reflector?

Message-ID: <uq7m0gh4lgde1a@corp.supernews.com>
Source record: 133363

It's actually a little more complicated than that. If you begin with a dipole a quarter wavelength above a perfect, infinite reflecting plane, you have a reflection that completely adds to the outgoing signal from the dipole. But the mutual coupling between the dipole and the current induced on the ground plane (which is the same as between the dipole and a fictitious "image") raises the dipole's radiation resistance. Because of the raised resistance, a given amount of power produces a smaller field from the dipole itself than it did when the dipole was in free space. This is why the gain isn't quite 6 dB greater than for the same dipole in free space, even when everything is perfect.

As you move the dipole closer to the ground plane, though, the radiation resistance drops, which increases the dipole current and resulting field. But now, the phase of the reflection isn't quite right to fully reinforce the field outward from the dipole. Nevertheless, because of the increased dipole current, the overall gain continues to increase as the dipole is moved closer and closer to the reflecting plane. You might recognize this as being exactly how a W8JK antenna works and, in fact, the pattern, gain, and element feedpoint impedance will be the same as for a W8JK. The gain hits a maximum of just under 7 dB relative to the free-space dipole when the dipole is very close to the ground plane, despite the nearly complete cancellation taking place at that spacing between the outgoing dipole radiation and the reflected radiation. However, you'll never get this in practice. As the dipole gets very close to ground plane, the radiation resistance drops and the current increases dramatically. So even a very small amount of loss in a real antenna (or reflector) can more than cancel out the gain you might have achieved.

Between real losses and a finite ground plane, in a real you'll see gains more like what Richard quotes Bailey as giving.

If the dipole is much more than a quarter wavelength above the reflector, you can get a gain of around 6 dB, but with lobes pointing away from the center.

You can easily observe all these effects with the free demo version of EZNEC.

Roy Lewallen, W7EL

Roy, W7EL wrote:
"You can easily observe these effects with the free demo version of EZNEC."

That`s like a broken drum. You can`t beat it.

Never the less, when your gain is almost 6 db, your volts per meter have almost doubled and your power has almost quadrupled. That`s simple mathematics which trumps the other sciences.

The antenna with the reflector is the only source of the energy. Interaction in the source causes the energy concentrtion. There is imperfection because perfection is unattainable. I tried to be succinct but not too succinct.

I did not give Bailey`s spacing between the folded dipole and its reflector. It was 0.127 wavelength. The dipole was parallel to its "extensive" reflecting surface.

Bailey says his dipole`s feed impedance drops from 300 ohms to 150 ohms with the reflector in place.

I assiumed that Bailey had picked the spacing for maximum gain. Maybe he could have done better. I still think that 20 db is too much to expect or believe.

Best regards, Richard Harrison, KB5WZI

I dunno ... what about tuning the director for 10m, the reflector for 11
and the active element in between??

I agree you should not let trees keep you off the air. Trees are just a challenge.

Almost 50 years ago I worked at the world`s largest shortwave broadcasting plant, it was thought at the time.The plant had recently been sited on a wooded plain of about 500 acres. The trees were clear cut and the stumps pulled before the first antenna, a rhombic, was erected to be driven by a transmitter in a group of trailers. This first 10 KW transmitter was soon joined by many 50 KW and 100 KW transmitters in permanent settings.

Point is, the trees would have been detrimental to the shortwaves so they were cut.

Best regards, Richard Harrison, KB5WZI

Why not put up a big loop IN the trees...mines that way and works great. Get all the open space you can but if you can hang 120 meters of wire and have tuner...it will be awesome!! 73 Murray

> considering it.

It's hard to say which is "better". Both antennas seem to be favorably reviewed on eHam; you might want to have a look over there to see what people have to say. The MQ-2 is a bit smaller and lighter (4.5' boom, 12.1' elements for the MQ-2; 7.3' boom and 17.1' elements for the MA5B). Either will be a big step up in performance from a dipole.

The MQ-2 claims to offer some gain on 17 and 12 meters; the MA5B is simply a dipole on those bands. The MQ-2 also claims to work on 6 meters, but the SWR chart shows that you'll need a tuner on that band - and most HF tuners won't work well on 6. The MA5B claims a higher F/B ratio on 20M. The manufacturer's claimed gain figures for the MQ-2 are higher than those for the MA5B, but such numbers typically don't mean much (though the claims for the MA5B actually seem, for a change, to be realistic). I would expect the MA5B to have slightly more gain because of its larger size; neither will match the performance of a full-size antenna.

The sort of people who put up these small beams aren't likely to be doing a lot of antenna experimentation; they usually suffer from space and/or budget limitations. So you're not likely to find many people who have used both antennas, which will limit the direct comparisons.

Based on the reviews, both are much better than the Mosley Mini-33, the only other currently available direct competitor in the "tiny beam" category that I know of.

Bert,

Many 10 m antennas claim they cover the whole 10 m band, which is 1.7 MHz wide. So, if you make your antenna resonance 27.4, your coverage will be from 26.55 to 28.25 - not very useful. If you make the antenna resonant at 28.25, your coverage will be from 27.4 to 29.1, which will cover everything except the top end of 10m without a tuner. Assuming this antenna is horizontally polarized, your father will have to use a horizontally polarized antenna on his CB (like a dipole). If you set up your beam for vertical polarization, it will work for 10m DX, but lousy for 10 m local contacts. If you are a 10 m FM fan, you are probably outta luck.

The HexBeam is only 11 ft in diameter. And it is made mostly
made out of wire which is much more invisible than metal
tubing. And it is more broadbanded than the other antennas.

Thank you for your kind words but most would say that
you over estimate my abilities.
What I did find interesting was that the German inventor
was also invoking the 'dual loop' aproach as advocated
in the ARRL antenna book , to cover all the bands,a direction
I also have taken in the past as well as using only one
loop as an antenna for a particular range and then evolving
towards adding the transmission line to make the set up a
'antenna system'.
In the past I have used both variable inductance and variable
capacitors to 'stretch' the frequency range of a single loop which
appeared successful
Unfortunately at that time I was using step motors with unshielded
power lines so the noise level was too high to enjoy it.
Never did understand why the commercial builders did not follow
that approach but then they are a lot smarter than I.
Today I am duplicating that setup but using D.C. motors which
unfortunately are not pulsed but should allow me to have some
fun on the bands now winter is aproaching and I have to put my
experimenting aside (which is my first love)
Best regards
Art

Gentlemen As a former Brit I still retain my love of experimenting
with
antennas and thus over the years have accumulated quite a pile of
aluminium tubing.This pile is being shipped off to the scrapyard by my
grandaughter because I have little use for it anymore.
The reason from moving away from aluminium is that I find telescopic
fishing poles to be much more available,less expensive, can be
extended to over
320 inches aside using aluminium in the boom area, Can use wire inside
or aluminium paper on the outside so the basic rod material used lasts
for ever because modification to length over experimental time does
not damage the pole itself.
P.S.
When an ice storm comes along the rod believes it has caught a fish,
it bends as all fishing rods do and the ice slides off !

Bert, WA2SI wrote:
"....is it better to tune the Yagi to be resonant on 28.444 MHz and use the tuner for 27.405 MHz, or the other way around?

Will Hy-Gain supply the bandwidth and other antenna characteristics? Can you determine the antenna characteristics for yourself?

A 3-element Yagi with 7%-8% bandwidth shouldn`t be too difficult if big enough rods are used. It takes 8%-10% bandwidth to cover TV Channel 2 at 54 Mhz-60 MHz.

Why not just give the Hy-Gain a try as-is?

If an antenna is a little too long, a capacitance in series is usually needed to tune it. I would be inclined on insufficient data to try retuning the antenna resonant on 27.405 MHz to a higher frequency using my tuner.

Best regards, Richard Harrison, KB5WZI

> bugcatchers. Big fat low loss coils. MK

I make one that is 3" dia, about comparable to Henry Allen's bugcatcher. I
have found that
that is about the best compromise in a mobile HF antenna. If you go much
larger, you'll spend
a lot of time re-tuning because the Q reaches such a point that any and
everything you encounter
as you drive will mess it up--or your auto-positioner will go nuts
"hunting".

What that guy you mentioned is doing (I think) is "transformer winding" his
coils--so closely winding
the coils that the resistance reaches a point where no feed point device is
needed. Of course, it is
a bad idea. That's the same way many hamsticks work so they need no
matching. I make all of
mine with #14 wire at 8 TPI which makes for a good coil form and spacing.
You DEFINITELY
have to match the Carolina Cyclones. That's where I run into trouble with
newbies. Sometimes
they will call and complain that they can't get their new antenna to work.
I then have to explain what that "other" coil in their package is for. They
don't have time to read the instructions, I guess.

Bert,tune the antenna for the C.B. channel for maximum gain since that
is a groundwave transmission The 10 metre you can apply power as you
wish to be heard, besides that transmission relies on bouncing off of
the ionasphere so it is not a problem regarding power if you decide to
run your antenna vertically
polarised.

Straighten out an old hanger and replace the whip in the ferrule with it.
Cut it down to length to see
if it'll work. Then you can cut your whip to length.

now THERE'S an idea...already calculated, based on the current whip
length, how short the new one should be...

thanks!

yeah i trimmed about 3" off the current whip...didnt shift it out of
the 2m band at all...so it will take some work...

Oh, the economy in general, some problems with towers maybe falling down,
threats of lawsuits, the usual stuff...

Last I heard, they had solved all the real problems, i.e. the towers maybe
falling down and lawsuit stuff, but you still have the general economy
problems and the perceived stock value problems.

If it makes you feel better, I bought Rohn when they were about $6.

Buy more? Sell? Get drunk? Go to Vegas 'cause the odds are better?

Gee, the stock market is fun. Let me tell you HOW much fun it is.

Hi,

I think to buy a buddipole (http://www.buddipole.com) for portable operations with some of its accessories.

About the installation of the dipole (2x 2.5m) itself on its tripod, I have the choice to place the tripod at ground level (0.5-3m high) or, alternative to place the tripod on top of my car or on the cap (it's a golf) from which I can erect it 0.5-3m high also (however under windy conditions I 'm sure it will stay in position without small magnets fixed at the tripod base).

Question : being metallic and highly conductive, is the car top or the cap a good place to install such short dipole or it should be better to place it away from the car (which motor is switched off), in the grass or on the macadam and as high as possible above ground to benefit of a better radiation angle ? Car or field/grass/macadam ?

Thanks.

Thierry

Cross-posted to: alt.ham-radio.marketplace,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc,rec.radio.cb,rec.radio.swap

I have 60 feet of Rohn 25 available in North Jersey. This is a package deal which includes:

One top section with rotor plate and guy brackets
Five regular sections
One short roof mount base with foot plates
One ground mount base plate
One house bracket
And, Three philystran guy cables with attached hardware.

This is pickup only as I no longer have a truck to transport it in.

I will take $350 for the whole package or possibly trade for something of equal value.

73, de Rich

558. For /P ops, screwdrive/whip or dipole ?

Source record: 133299

Hi,

Without speaking about beams, I would like to use for portable operations (mini trips, holidays, etc) either a screwdrive antenna (2-10m high) or a (buddi)dipole 5-10m long (max.).

I'm searching an HF (at least 40-10m) mobile antenna fine for DXing, light, easy to install and remove without permanent installation.

What could be the advantage of using a screwdrive antenna vs the second model knowing that I move most of the time in car but from time to time by foot/plane also if we speak of holidays abroad.

The dipole seems easier to collapse and transport, and should allow me to avoid a permanent installation on the car.

Now about their performances : what model should be "better" for DXing, knowing that the buddipole comes with rotator arms and screwdrives seem to be know for their huge loss ?

Some ideas to share about portable operations and brands to suggest (i known nothing at all about screwdrives and their performances vs dipole, true vertical, etc) ?

Thanks

Thierry

My 2 cents-
I was under the impression that the reason to use ladder-line or
window-line or twin-lead (regardless of 300,450, 600 ohm)
is the fact that it is "Low Loss" - (oh, and cheaper than coax) - even with
standing waves, more signal can get to the antenna. I've used 300 and 450
ohm ..
. - all ya gotta do is is wind a balun to match the impedence - or make up a
matching section -
then you can run a long line without the loss of coax. even at vhf

There was an article in an old 73 magazine that described the "Super Gainer 40m dipole". It was a folded dipole made from tv twin lead and fed with 50 ohm coax mounted 7 ft. off the ground with 3 reflector wires laying on the ground underneath. The author claimed 20+ db gain for local stations, about 300 miles max vs. a high dipole. I tend to believe this after doing the same with a low 40m loop.

Do a search on: "slinky antenna". I got 1591 hits on a simple MSN search.

In 1949 one of the operators at the KPRC / KXYZ transmitting plant where I worked was a radio amateur, James L. Davis, W5LIT, now SK. "J.L." replaced the base loaded whip mounted on the rear bumper of his new Ford with a bamboo fishing pole of about the same length as the whip. He wrapped enough turns of wire around his pole to resonate without the base coil. He swore the performance was much better on 75 meters. The difference I noted was that after the replacement he frequently fired off a corona from the tip of his fishing pole antenna. I wasn`t paying too close attention to his ham operations, but that corona did get my attention.

Best regards, Richard Harrison, KB5WZI

It sounds like a Super Scanner C.B. antenna which allowed you to
switch to 3 different directions with the remaining two verticals
acting as reflectors.
The radial forms carried coax of a suitable length from the driven
vertical.
The problem is that this requires THREE relays and you only mention
TWO !

No, but you can get some really odd things with a satellite dish that isn't properly grounded.

Take a look at how the installer grounded the sat dish... Most don't do much of a job of it, and some leave off the ground connection altogether. This is a recipe for disaster, particularly if you're in lightning country... and it can make for strange operation if you have high RF fields nearby...

Stargazer,
Typically, a satelite dish shouldn't be affect by HF
signals. But, it ~can~ be if it isn't installed correctly.
The dish's feed line can carry RF from the HF radio into
the house like any other conductor. What happens when it
gets into the house is anyone's guess. Treat it like you
would any other RFI problem.

Brent,
Okay. I don't know about the 'stronger' part, but
bandwidth isn't going to be affected too much by using
coax as the conductor (seriously doubt if bandwidth is
affected at all). That doesn't mean I think you shouldn't
do it.

Dear Thierry,

BTW In America the "golf" model from VW is sold under the name of "Rabbit".

The general rule for an horizontal dipole like the one you speak about, is to be erected the highest possible. The roof top of your car being about 1.5m above ground, you may use the frame of your car to attach your dipole 1.5m higher. The result must be very similar between this solution and the antenna posted above ground with the same pole or tripod.

73 de Jacques - ON5MJ

It is just inductor, sitting above 4 "radials" that resonate the 18AVT on 40 m.
There are no capacitors in the top coil (unless it uses inter-turn capacitance)
. I took it appart and seen it with my eyes. Coil is inserted in the fiberglass
tubing sleeve.

Source record: 133316

Well, I measured my loft last night. I have two separate attic spaces, which could be connected by drilling a small hole in some plasterboard. I have about 18ft available space in each, so theoretically, could put up a 36 ft or so dipole (which would get me nicely onto 20m which is about 33).

Question is this: Because this space is in the apex of the roof, there's no way I could set a dipole's legs out straight. They would be slightly s-shaped (not massively off though). Is that likely to make a big difference? There would need to be some support at these bends, probably by way of pulling the leg one way or the other with a cord of some sort.

If so, would you say that a stealth antenna on the roof (maybe one of the Isotropic things) is better than a slightly crooked dipole in the attic? I appreciate there's a whole bunch of variables to that question, but as a general rule of thumb?

Oh, cost is also a factor - dipole's are very cheap, Isotropics are quite expensive for that they are.

Thanks,

D

if you want to play on HF why dont you use hamsticks and the dipole adapter that they sell on hamsticks website i think they would only be about 14-18 foot long total and should work well for you
sure beats giving yourself a head ache trying to figure out an attic dipole

Hello,

You may want to contact hy-gain customer service... I ordered a trap from
for an old vertical a couple of months ago and they were able to replace it.
The cost was very reasonable. They are slow, but it's worth the wait.

A "slightly s-shaped" dipole should work just fine. You can lower the
resonant frequency by adding a capacity hat to each end. A-frame attics
are ideal for end hats.

Put it up. The 's' shape won't matter. It will work, tho this assumes
non-metallic roof material. Just keep it away from all metal objects as
far as possible.
I like to use nylon cord and small nails to suspend it a few inches
from the wooden roof structure. There are considerable RF voltages in so
me places on antennas and you want to preclude any possibility of
arcing.
Your main problem will be with RFI in the household when you run much
power. You may need to keep your power level down to 25 watts or so if
that proves to be a serious problem. You'll be determining that for
yourself.

> If so, would you say that a stealth antenna on the roof (maybe one of the
> Isotropic things) is better than a slightly crooked dipole in the attic?

Emphatically, NO. Attic Dipoles, even compromised ones, should be much
better.

Dick

Hello,

A dipole is the way to go... Just be sure to cut it a little longer than
your preferred operating frequency. It's easier to prune and tune than
solder and curse.

No. I have found no circumstances where any HF band tx causes problems for my DirecTV system.
(500w 40 dipole, 500W T-6 13-30 mhz log @ 52'). The dish is about 75' from the tower.

Nor have I found any problem with 2m or 70cm at 160w out.

I've seen the question asked many times, and have never seen a report of interfernce to DTV.

Many thanks to all of you for that advice, I think I'll go with the attic dipole which seems to be the majority opinion.

Just one thing though, these capacitive "hats" that I keep hearing about - where do you get them, and how do you tune them exactly?

And presumably they just mount at the end of each leg of the dipole?

By the way, I don't anticipate too much EMC problems - I'm only licensed for 10 watts (Foundation Licensee) anyway, so won't be running more than that.

Cheers,

Dean

I like the look of the Hamsticks antenna's. 7ft high vertical for all hf bands.

Are these any good? Also, being designed for a vehicle, presumably I need to create some kind of ground plane on the roof? How does that work, or is it not actually recomended?

Yuri,
It's an 18AVQ, not the 18AVT. It was discontinued around
1970(?) when newer models came out. The traps were all
in metal 'cans' which made up part of the capacitor.

Use both. There are times each could be better than the other.
>
> I'm searching an HF (at least 40-10m) mobile antenna fine for DXing,

Better close in performance on the low bands for one thing, using the
dipole.
>
> The dipole seems easier to collapse and transport, and should allow me

I use portable dipoles often when out portable. Hard to beat for the
$$$ involved. I sling through any nearby trees, or take my own mast if
needed.
>
> Now about their performances : what model should be "better" for
> DXing, knowing that the buddipole comes with rotator arms and

Just depends on the band, etc. Each would work. Screwdrivers huge
loss???
Someone is taking you for a long ride...:(Only the cheap poorly made
screwdrivers are overly lossy. The best ones are near, or at, the top
of the heap.
>
> Some ideas to share about portable operations and brands to suggest (i
> known nothing at all about screwdrives and their performances vs
> dipole, true vertical, etc) ?

Dunno. Dipoles are cheap and easy to make, even on the fly. Just throw
a spool of wire in the trunk. You could take a small tuner and ladder
line, and feed a single 40m dipole with good results from 40-10 m. Or

make single band dipoles fed with coax. You can't really put a number on the comparitive performance of each type. Some paths and bands the dipole would win. Some , the vertical mobile antenna. MK

P.S... I also use a beam portable on occasion. Not nearly as hard as
you might think, but a little more work than a simple dipole. Here's a
shot of mine at the last field day.. It all fits in the back of that
old truck. http://web.wt.net/~nm5k/fd34.jpg

Doc, W5LZ wrote:
"(seriously doubt if bandwidth is affected at all)."

This was in response to using a fat antenna conductor versus a thin conductor.

Experience from the earliest days of radio contradicts the idea that fat versus thin makes no difference. Large antenna conductor cross section lowers Q.

Multiple paralleled wire antennas were used in early times to lower radiotelegraph character distortion. In recent times conical antennas have been used for better TV signals.

Arnold B. Bailey has a simplified explanation on page 303 of "TV and Other Receiving Antennas":

"If the surface is a thin wire, resonance will occur sharply at one frequency, predicated by the small point at which reflection of the wave occurs at the open end of the wire. Here the transition at the open end of the wire is abrupt and finite. If the configuration is such that a large metallic surface is involved instead of a thin wire, the wave traveling on the large surface, as it approaches the free end of the antenna, will tend to flow around the end of the antenna rather than be abruptly changed in direction. This tends to make the antenna les frequency sensitive----."

No mathematical proof, but some speculation is better than no explanation at all of an often observed phenom`. Does a capacity hat improve bandwidth? A ragged end would seem more promising to me.

Best regards, Richard Harrison, KB5WZI

> versus thin makes no difference. Large antenna conductor cross section
> lowers Q.
==========

To see a significant and useable difference in Q and bandwidth on an 80m
dipole it is necessary to change the antenna conductor from an 18-gauge wire
to a 3-feet diameter cage of enormous weight and collapses every winter
under wind and ice loading.

In any case, any broadening of system bandwidth can be more than nullified
by the effects of the feedline and TUNER Q.

The number of times this subject appears on these walls is entirely out of
proportion with the magnitude of any effects on bandwidth.

Yours Reg.

Ok, go for Golf then...

Ok also to use the ground in place of my car. It will be easier for me to place the dipole at ground level, may be on top of a longer mast (3m high) to reach "higher" heights when working in the field.

Hi,

The dipole is the right track... You probably wont even need a capacity hat if the antenna is cut to full size for 20 meters. A capacity hat is just a circle made out of metal or wire added to the ends of the antenna to electrically make it look longer (lower frequency). Imagine a wire with the end connected to the center of a pie pan.

Source record: 133238

How far off resonance do you have to be before using coax
will significantly affect the antenna system performance.
I'm still using a tuner to get a 1:1 SWR.

I have about 4:1 on the bottom of 80 m and tune it out with
the tuner.

Also.... For 30 m what would be the best off resonance
antenna... A 40 m dipole, 80 m dipole or an Inverted-L for
160 m.
I swear I see a shallow null around 10 MHz with the Inv-L???

599. How come there are shallow nulls with dipoles on other freqs??

It depends.

First what is it's loss without the high swr. From that you can go to
tables or calculate the additional loss from the swr change.

Next how high is the power is you are running. At high swr and high power
you may exceed the voltage rating of the cable.

And last but not least, how much loss can you tolerate.

>
> I have about 4:1 on the bottom of 80 m and tune it out with
> the tuner.

if you have 1db of loss to a dummy load at that frequency and add the 4:1
swr you will add about .8db more loss due to the swr. if you started with a
really bad 3db of loss you would add another 1.5db. so i would say to
ignore it unless you have an extremely long and lossy coax.

>Whats up with that??

I assume you mean your swr bridge shows an swr below about 3:1 on frequencies other than 1.9 mhz. It is entirely possible that the impedance of your antenna at frequencies other than 160m may yield an swr below 3:1. If this is true, you may have yourself a "multiband" antenna, which has an acceptable swr on more than one band.
An antenna designed for one band may have an added benefit with a low swr on other bands. Depends on the physical dimensions of the antenna, and the frequency it will be used. Some "multiband" antennas of note are: G5RV, OCF Windom, a 40m dipole used on 15m, among others. I suspect some of the "multiband" antennas were designed for one band, and found out by accident that they will work quite well on other bands.

Source record: 133245

On 80 meters that is insignificant. If you make the TX happy you will do fine.

I use my 160m Inverted L on 10 mhz with good results via a tuner of course. I have also tried my 75 meter dipole via a tuner. The inverted L worked better.

My inverted L is about 190 foot long. And not quite a L. Comes toward earth at the far end. Works well on all bands actually. Bit troublesome on 80 tho. Had to add some doorknob caps to it,

Hope that helps some.

StarGazer,
It's called harmonics. You will probably find a
fairly decent SWR on twice, three times and four times
the 160 meter resonant frequency. It's normal...
'Doc
PS - and for multipliers of greater than 2-3-4 times
the resonant frequency also.

I think the autor was getting his gain figures by comparing a high dipole's response to low angle strong short wave bc signals to that of a low dipole's response to short skip stations. In other words, on the low dipole, the sw station could be 20db down while the local stations 10db stronger resulting in 30db gain. Sorta....

Depends on the length of coax. Maxwell, W2DU makes an argument in "Reflections" that it doesn't matter where you put an antenna tuner on mobile installations. You can put it at the base of the antenna, or at the transmitter, only if you have a fairly short length <25' of low loss coax. Using a short length coax with a high swr, or a longer with a 4:1 swr and a tuner should be ok.
>Also.... For 30 m what would be the best off resonance
>antenna... A 40 m dipole, 80 m dipole or an Inverted-L for

The EZNEC demo should answer that.

>I swear I see a shallow null around 10 MHz with the Inv-L???

Thats entirely possible. Antennas can show low 50 ohm swr on more than one frequency. An example is a 7 Mhz dipole showing resonance on 21 mhz. The 7 is a half wave, and the 21 is a three half wave dipole.

==========

Dear Stargazer,

Absolutely nothing up with it. ;o)

Bear in mind the most inaccurate of all so-called measuring instruments is the SWR meter. It is not even a meter.

It doesn't even measure SWR. How can it - there's no transmission line on which to measure anything !

It merely INDICATES whether the load on the transmitter IS in the 50 ohms ballpark or is NOT in the 50-ohms ballpark.

It is only necessary to know, and it is quite sufficient to be happy about, that all is satisfactory and in good working order while you are transmitting. It is indeed an essential instrument. But do not allow the misnomer to distort your imagination about what is actually happening.

A far more logical, descriptive title for the very misleading /confusing name of SWR meter, in this 21st Century is -

TLI = TRANSMITTER LOADING INDICATOR which I see signs of coming into use.

It will of course take some years before it is universally accepted and the greatly misleading misnomer disappears from instrument faces, handbooks, periodicals, newsgroups, and other forms of communications between guru's and radio amateurs such as radiowaves.

Regards, Reg, G4FGQ.

612. Re: Is a car top a good ground ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-10 23:28:10 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <ao52eadbd2@paris.btinternet.com>
Source record: 133250

The equivalent circuit (a model, a part of the whole system) of a car body plus ground is a very short and very fat transmission line with a capacitance between the underside of the car and the ground surface.

Then, in series with the capacitance is the resistance of a slab of soil in series with the zero resistance of Mother Earth herself. The thickness of the slab is equal to the RF 'skin depth' in the soil.

The car body (the short, fat, single electrical conductor) does of course have a radiation resistance which becomes a part of the whole system.

The electrical network is completed by incorporating the antenna itself, loading coil, top-hat, tuner and stray capacitances from the antenna to car body and to ground surface - the ground surface soil resistance once more being taken into account.

It is all quite calculable and can be incorporated in a computer program to analyse the radiating performance and other charcteristics of short antennas mounted on vehicle roofs. Any competent engineer can do it.

The most difficult problem is due to the fact that vehicles don't stay still over different types of ground. ;o)

The real sadness is that arm-chair calculations take all the fun out of shoot-outs.

Brian,

I've seen the fuzzing fiberglas scenario numerous times with embassy repeater antennas and with the Cushcraft R-5 I used for 12/17m in Africa. I think the cause is breakdown by UV. I note that the fiberglas boom I used for my satellite antennas is coated with a black compound said to be for protection from UV.

617. First Wire Antenna Help

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-11 03:18:16 UTC
From: Joshua Goldsmith <NOTjoshin@starband.net>
Message-ID: <iqrp9.3953$KE6.1812026456@twister1.starband.net>
Source record: 133256

Hi all,

Having recently upgraded to General, I decided that I should (learn about and) make my own antenna and just finished putting it up. (Especially since toy funds are low with a 13 month old running about the house.) Unforturnately, it isn't turning out as well as I had hoped. My goal was 1 antenna that would tune 10m through 80m and maybe even let me try out 160m.

The antenna is a 440' horizontal loop antenna using insulated solid conductor 12 gauge wire. Because my property is pretty thickly wooded (and sloped), 3 of the corners are trees. The corners of the antenna are about 35', 65', 30', and 18' up.

The antenna is fed with 100' of Radio Shack's "high quality" 300ohm twinlead. The feedline is terminated at either the 4:1 balun inside my MFJ-962C or a 1:1 balun and then fed to the coax inputs on the same tuner.

The feed point is around 20' above ground and I've tried to ensure that the twinlead is perpendicular to both the ground and the antenna.

I am unable to tune this antenna very well. On the two bands I'm most interested in; 80 and 20m, I can't seem to get it to tune better than 5:1.

Since I'm new at HF operation, here's how I've been trying to tune my antenna (hints/tips are appreciated):
1) Find clear frequency near where I want to transmit
2) Set Transmit and Antenna Dials to midpoint
3) Adjust Inductor dial for maximum noise
4) At low power (5 or 10w) transmit a 30s long dah
5) Adjust Trans & Antenna dials for lowest SWR
If that doesn't work well, I change the inductor setting and go back to step 4.

What may be a clue to the problem I'm having is that I barely hear a difference between the various inductor settings (usually only between max and min). I've taken the cover off the tuner, looked for burnt spots, pulled out my multimeter to look for bad connections, and tried cleaning the inductor switch.

(The Transmitter and Antenna dials do seem to have an effect, it is just the inductor dial that doesn't.)

Any thoughts as to what's wrong? I did borrow a QRP tuner (Z11) and it can tune to about 2:1 but I'd like to be able to use my full 100 watts.

The antenna is the best receiving antenna I've ever had but I didn't learn code to listen. :)

Thanks!

-Josh (Nuke the NOT to e-mail)

For an A-frame attic, the dipole with hats might look like:

```
+ +
/ \ / \
/ +---\-------------X-----------/---+ \
/ \ / \
+-------------+ +-------------+
```

Where X is the center of the dipole and the two triangles are made
out of hardware cloth which probably should be mounted on stand-
off insulators. Someone did this earlier and it worked like a
charm.

Brent,

I've been using the 160m coaxial inverted "L" for 160 for over a year now and am delighted with the performance. Remember to feed the shield and run the center conductor to ground. I found that I had to add about 3 feet to the antenna to achieve resonance at 1850. The antenna covers the entire band with under 2:1 SWR. Mine runs vertically for sixty feet and I have about 2500 feet of radials installed.

One additional hint: Where the antenna bends from vertical to horizontal, I used a heavy insulator which has one end fixed to the tower. The other end supports a solid brass pulley with a wheel diameter of about two inches. That keeps the cable from having a sharp radius at that point.

It is a function of the matched line loss of the coax, the
frequency, the SWR, and how much loss one is willing to tolerate.
The ARRL Handbook and Antenna Book have the necessary charts
to answer your question.

Assuming your inverted-L is 1/4 WL on 160m, you will obtain
additional resonances around 3/4WL, 5/4WL, 7/4WL, etc.

> Hope that helps.

That is not correct, Brent. If memory serves, you need about 104 feet of coaxial cable for the first portion. The shield is fed and the center conductor is grounded. The far end of that portion is shorted. The remainder of the antenna is made up of another piece of coaxial cable which is shorted at both ends to simulate a "fat" wire. What you end up with is half of a double bazooka antenna which includes a 1/4 wave shorted stub.

The answer is bandwidth between 2:1 SWR points. My 160m coaxial inverted "L", constructed from N4XX's CQ magazine article of a year or so back covers the entire 200 KHz of the band at under 2:1 (actually more like 1.7:1) while my conventional 80m inverted "L" using a series capacitor has a 2:1 bandwidth of only about 100 KHz.

I don't use a coaxial inverted "L" on 80m because the band is 500 KHz and SWR would likely be excessive at the extremes. I use relays to switch padding caps in and out on the conventional inverted "L" (and I don't rely on it as my sole 80m antenna.

Changing the length of the feedline will probably tune it in on 20m.
For 80m you may need to change the length of the antenna. Borrow an
antenna analyzer like the MFJ259B and look for resonant frequencies.

I like to leave a dipole a little long. If you're using a tuner then
you will add a little capacity to tune it instead of inductance. Seems a
bit easier to tune. Even without pruning.

Isn't it the length to diameter ratio that matters? In an 80 meter dipole it wouldn't perceptibly matter whether the wire used is 24 gauge or #6. On the other hand, use of a 36 inch cage dipole would definitely broaden the bandwidth.

Richard,
What you are talking about is the "k" in the formula
(492 X k) / f = L. If you will try a few different 'k's
in that formula you will find out that there isn't much
difference until you get to a quite sizable 'k' in relation
to the frequency in use. On 160 meters, the conductor would
be about the size of an average rural water storage tank.
But, at 400 Mhz, a conductor about the size of a Bic pen would
work great.

Thanks again for your help. I'll start experimenting at the weekend.

Ultimately, I may have to have the dipole a little short and maybe try loading it in the middle or at the ends. Alternatively, I liked the idea of putting the whole thing into a square. I should be able to fit that in at full length.

Hi Josh:
Sorry your having problems. I have a very similar setup for my antenna here and it works great with an MFJ 901b tuner. So yours should work also.. When you use the balun in the tuner did you remember to connect the jumper wire to the balun on the back of the tuner.. I believe that most mfj tuners require a jumper to active the internal balun. You did not mention how the antenna is tuning on the other bands. if it is tuning on other bands ok , then I would try lengthening or shortening the feed line a few feet at a time until the bands you want are tunable.. Mine is fed with about 25 ft. of 300 ohm line and works all band no problem.
don't give up keep trying.. it will work !

Hi!

A fellow ham's son is studying Electrical Engineering and
he was given as a project, the measurement of voltage, current
and phase angle at the feedpoint of a vlf antenna, with
digital indication. As this subject is somewhat off-topic
to his curriculum, he is looking for some info on the subject
to get him started.

I searched the net but seems there is little design info on
this subject. Me and my friend would be greatful for any
pointers to any material on this subject.

My thanks in advance

Hello,

I would suggest checking your feedline for any breaks or shorts and try changing it's length a little (80 and 20 are harmonically related and changing the length may help). Is the feedline near any metal objects? Check the connections on the tuner again... On some MFJ tuners you may find the binding posts are not making good contact. What type of ground do you have connected to the tuner? I would suggest borrowing another manual tuner to see if you get the same results.

Instead of remarks like "horse hockey", perhaps David or someone else could elaborate a bit on the theory behind the increased bandwidth?

The original information on the "double bazooka" turned out to be terribly flawed and the improved bandwidth either didn't exist, or was the result of identifiable losses.

Would someone please comment on the actual construction of the antenna, and the supposed mechanism of the increased bandwidth. I have a spare cross boom on my tower that I would like to put a 160 antenna on, and this might be an interesting experiment. I don't want to go to the bother, however, chasing a mirage.

Thanks for any details and analysis you might be able to provide.

Dick Carroll wrote:
"Isn`t it the length to diameter ratio that matters?"

Sure. With r-f, things are a function of frequency and expressed in terms of wavelength. All is scalable. A "lomg wire antenna" is long in terms of wavelength regardless of its length in meters.

" Fat wire" or "thin wire" is also in terms of frequency or wavelength. Either expression is OK as they are reciprocals. A fat wire is a much smaller fraction of wavelength than is a long wire antenna but the principle is the same.

A "savvy crowd" understands "long wire antenna" and "fat antenna wire".

A large (in terms of wavelength) cross section conductor antenna wire lowers Q.

"A fat wire has lower Q" is more succinct.

An antenna has a Zo. Like a transmission line, its value is sq. rt. of L/C. This is identical to the reciprocal of (vC), where v is the wave velocity and C is the capacitance per meter.

Zo of an antenna wire varies inversely with its capacitance. A fatter wire lowers Zo.

X/R is the antenna Q. A large antenna conductor cross section increases antenna bandwidth.

The change from small to large is continuous. How much Q it takes to be significant depends on your requirements.

Best regards, Richard Harrison, KB5WZI

The replies to this post that I have read seem to assume that a tuner in the shack can change the SWR on the feedline between the tuner and the antenna. Not so. It can only change the SWR on the piece of coax between the tuner and the rig. If it is desired to change the SWR on the feedline between the antenna and the shack, the tuner must be located at the antenna base or terminals.

Probably "spun out of" the 1930's technology that provided this type
of noise cancellation feature in the BC312 (or was it the BC-342)
receivers. I operated some of these in the early '50's in the Air
Force, and was impressed with this feature that never (back then) made
it into ham gear.

I wrote:
"How much Q it takes to be significant depends on your requirements."

For telegraph, baud rate, the reciprocal of the shortest telegraphic element, increases the required bandwidth of the radiotelegraph system. See Laport`s "Radio Antenna Engineering", page 37. At low frequencies, antenna bandwidth becomes a limiting factor. Ed Laport notes that enough bandwidth is needed to avoid distortion and the antenna must be tuned to the right frequency to get the signal through the passband.

Ed calculates that Telex transmitted on a 40-KHz carrier needs an antenna Q of no more than 235. In fact, he says that is the maximum Q for the whole system.

On page 38, Laport says: "One method of increasing bandwidth is to use an antenna of very large cross section. A cage or tower is more effective in this respect than a single thin wire."

Laport is considering 40 KHz. At 4 MHz, size in terms of wavelength is divided by 100.

Well, my 5 cents worth is, that with this and most other antennas, the
higher and free of obstructions, the better.
It has a quite flat radiation pattern, and the antenna is easily detuned by
near by obstacles....so it performs best with an open view to the horizon.
When you make adjustments to length of the sections for each band near the
ground to tune it for best SWR, you will also see that it has changed when
you move it up in position.
When I had mine up above the roof, it worked fine fine, but could not help
being afraid for a hit during thunder storms....but luckily nothing of that
sort ever happened!
I find it a great antenna, and so nice in use as you do not need a tuner!

I even used mine on 80m (with a tuner), and as I remember, Cushcraft replied
to me, that up to 100W on 80m was OK.

Neoklis wrote:
"---given as a project, the measurement of voltage, current, and phase angle at the feedpoint of a VLF antenna."

An oscilloscope?

VLF measurements are similar to those at medium wave or HF and the same instruments are usual.

Manuals for phase and current monitors such as the old RCA WM-30A and its successors may be helpful.

John E. Cunningham was a principal at the Cleveland Institute of Radio Engineering and they offered correspondence courses in broadcast radio that you often saw advertised in popular radio magazines. John`s face was pictured in many ads.

An operator at KTHT where I worked for about 10 years, took the course and sold his directional design and other services to a number of stations. He is now SK having accidentally electrocuted himself at KVOO in Tulsa.

I never took that course, but John E. Cunningham wrote a book, "The Complete Broadcast Antenna Book", which I highly recommend for its directional antenna chapters if you can`t find an old Cleveland Institute correspondence course.

Another must have is Ed Laport`s "Radio Antenna Engineering" which begins with Low-Frequency Antennas in Chapter 1, and thence continues with Medium-Frequency Broadcast Antennas in Chapter 2, and Chapter 3, High-Frequency Antennas, etc. .

Terman`s "Radio Engineering" is priceless.

Source record: 133186

When using a resonant antenna, antenna tuning is the process of adjusting the antenna to be resonant at the frequency of interest, and adjusting the matching device from the antenna to feed line so that the impedance of the antenna is close to the impedance of the feed line.

When using a Non resonant antenna, antenna tuning usually refers to the adjustment of the antenna matching unit to provide the proper impedance to the radio.

When using a TUBE type radio with a (limited range) matching section in the radio, you often need a reference to tune into. A dummy load provides that reference.

When testing any radio, a dummy load provides a reasonable non reactive match to the radio for testing. It also radiates far less than an antenna, so you create less interference to other users while testing.

>Could anybody explain to me what is antena tuning and what dummy loads are
>used for?

In general antenna tuning refers to adjusting various components of your
antenna system, to make your antenna system work as well as possible.

In general a dummy load is a 50 ohm non reactive resistor capable of
disappating large amounts of power. It is connected to the output of your
transmitter, so the transmitter can be checked at full power. It can be
connected to the end of your transmission line in place of the antenna for a
full power test of the transmitter+transmission line. Since all of your rf is
turned into heat you will radiate very little signal, and won't interfer with
other stations while testing.

From a good old google search.
From: Merv Stump (W2FOE@worldnet.att.net@postoffice.worldnet.att.net)
Subject: Re: 160 meter "inverted L"
View: Complete Thread (2 articles)
Original Format
Newsgroups: rec.radio.amateur.antenna
Date: 1996/07/23

Adam, in the early 80's Coleman Rowland, W4TWW published an excellent article in CQ on the Coaxial Inverted L For 160 meters. I have built the antenna and found it to be excellent. In theory the antenna is 1/4 wave long and is made of a 50 ohm coax section and a 300 ohm twin lead section. The coax section is an electrical quarter wave (246/FMHz times the velocity factor) and the 300 ohm twin lead makes up the rest of the quarter wave.

In reality through trial and error Coleman, found that the total length of the antenna should be 230/FMHz; and the coax section should be 162.5/FMHz. For 1.850 MHz this works out to 88 feet for the coax and 37 feet for the twin lead for a total length of 125 feet.

Short the center conductor to the shield of the coax, and connect this to the twin lead. The twin lead is shorted at this connection point and also shorted at the opposite end.

Feed it at the other end of the coax, using 50 ohm coax from your rig and connect the center conductor of the coax from your rig to the shield of the coax making the antenna; and the shield of the coax from the rig to the center conductor of the coax making the antenna. The center conductor of the antenna coax goes to ground with as many radials as possible.

Mount it as vertical as possible and pull the rest out as horizontal as possible. If you can go up 88 feet it's good to get the entire coaxial section vertical, but if you can't it will still work well.

The antenna is very broad and will be useable across the entire 160 meter band without a tuner. However, it is still fundamentally a vertical so you need as many radials as you can possibly get.

I later made a change to W4TWW's design which I would recommend. I simply replaced the 300 ohm twin lead with another piece of 50 ohm coax. It's much stronger and I saw no difference electrically.

Good luck, Merv

The rule of thumb is BW is roughly the reciprocal of 3 to 5 times the
pulse rate. For the Q offered above it appears that the Telex rate is
something less than 60Hz (57 for 3x).

Richard, don't you think it would be a good idea to introduce a few numbers?
Then we can better see what it is we are talking about.

For example, what is the Q and bandwidth of a 1/2-wave 40m dipole
constructed from 18 gauge wire ?

And then, what is the Q and bandwidth of the same antenna constructed of 10
gauge wire ?

Reg G4FGQ.

I have a huge gopher problem here and they chew right through the outer
casing of such coax. netter to bury incased in schedule 40 pvc pipe. then
you can thread through a new line should the old one have problems.

660. Re: License plate mount for Hamstick?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-11 23:23:14 UTC
From: Bob Walker <bowalk@attbi.com>
Message-ID: <C3Jp9.6623$rz6.593@sccrnsc02>
Source record: 133199

I use the license plate mount with a Hustler. I can remove the resonator and get a decent match on 6 but I do not use 6. I used a mag mount first on the center of the roof. My test results are HF but the license plate mount tests better. HOWEVER, I now have a very good ground. The mag mount is not the best ground. A Saturn has a plastic bumper offset about 2 inches in front of the frame. "We" (KN4HX) drilled 4 one inch holes for access to the frame for the lower 4 of the 6 mounting holes, used spacers and long bolts to bolt the mount directly to the frame. Then used the original pem nuts and screws of the plastic bumper to mount the license plate on top of the license plate mount. The license plate is now mounted with the original top two screws through the plate and the mount.

I have the MP-1 and the B&W apartment antenna. MP-1 is better. Both work.
I suggest you forget 40 with both of them if you are QRP. 100 W may be OK.

That's the point. At HF if you use anywhere near decent coaxial
feedline the loss will be insignificant when you place the tuner at the
line input instead of at the antenna.
It's done for operator convenience. I can work the entire band by
retuning the antenna *system* from the operating desk. The difference in
my radiated power from the antenna resonant frequency to either band
edge is trivial.
Ask Walt Maxwell. Or check his book "Reflections".

My R7 shows a match in the lower 80M band. I should try it
as I only run low power (<10w) 99 percent of the time.
For 80M I normally use a trap vertical wire bent over at
about 30 ft.

I replaced my 25 year old HyGain 14AVQ with a Butternut HF-9V two
years ago and have been extremely pleased with it's performance. It
is ground mounted, and I haven't put any radials down yet, but I am
able to work world-wide DX with it using only 100 watts! Soil is less
than great for conductivity in this area.

The best examples of Helical design were the beams manufactured by Kirk W8FYR in the 1970's. Kirk had 2 and 3 element 40 and 2 to 5 el 10 to 20 beams made from fiberglas. I had a 5 el Kirk on a 42 foot boom. Kirk used copper tape and followed the Helical design in most handbooks. There was a review in QST in 1971.

One Contester(W4YWX now N4PN) had a 5 el 20, 15, and 10 stacked on a 96 foot Aluminum tower.

Kirk became a SK and the antenna were made by Viking Instrument in W1 for awhile.

The 5el 20 was not as good as the 5 el KLM but much better than a 3 el mono bander.
I feel with the newer computer modeling for spacing the Kirk Helicodial Beam should approach the gain and front to back of a full size beam. They sure were light weight!

Take a look at the design of the voltage/current pickups for
an SWR meter. Instead of adding those phasors, change them
to digital signals and measure the time between the rising
edges.

>The replies to this post that I have read seem to assume that a tuner
>in the shack can change the SWR on the feedline between the tuner and
>the antenna. Not so.

Not assuming that at all. A tuner in the shack is more convienent than at the antenna. The swr on the coax will be high at times with the tuner in the shack, but if the coax run is short, no problem.
> If it is desired to change the SWR on
>the feedline between the antenna and the shack, the tuner must be
>located at the antenna base or terminals.

True. But, if your goal is to radiate as much RF as possible with the least amount of hassle, put your tuner in the shack. If your goal is making sure your 50 ohm coax is terminated with 50 ohms put your tuner at the antenna terminals. The person listening to you at the other end of the radio circuit won't be able to discern a difference.

That's misquoting Maxwell by grossly over-simplifying. Where "at HF" - 10m or Top Band? How "decent" a feedline - how long, what's the matched loss? What's the SWR?

You can't skip over all these details, because they make all the difference between losses that are trivial, or losses that are large enough to put a 100W transmitter into the QRP league (and put a QRP transmitter into the noise).

Radio hams so often crave a single, simple answer - but here there isn't one. You have to work out what the numbers mean for your particular situation.

As K1TTT pointed out:

>>It depends.
>>
>>First what is its loss without the high swr. From that you can go to
>>tables or calculate the additional loss from the swr change.
>>
>>Next how high is the power is you are running. At high swr and
>>high power you may exceed the voltage rating of the cable.
>>
>>And last but not least, how much loss can you tolerate.

Until you've done all that, you don't actually *know* anything.

There's an Excel spreadsheet on my 'In Practice' web page (scroll down to March 2002) which allows you to input your own line type and length, and see graphs of line loss against frequency and SWR. The graphs update as you change your inputs.

Start by exploring the RG213 sheet, and then move on to the "generic lines" page.

>...

Hi,

Thanks Reg, but I always have had difficulties to "translate" these
models in practical data, usable in the field... even if I understand
well what you mean.
I am however happy to know we can modelize such complex structure
(car+ antenna) quite easily (for en engineer).

Practically I will proceed to several tests in the field, one placing
the antenna on my car, the other onto the ground, and I will see. Then
we could may be compare our both results, the theoretical ones and the
practical ones...

NB
Note about Gulf that some are like rabbits...with 130 or 150 PH they
easily exceed 220 km/h chrono, like mine, Hi !

Thanks for comments.

I got tired of straining to hear signals from AO-40 with my barbecue grill dish and developed a circular polarized antenna that WORKS! I talked a manufacturer into producing small quantities of these specialized AO-40 antennas, and I am now making this antenna available to the amateur radio community. It is an offset parabolic and there is NO aperture blockage of the incoming signal. Plus, you can connect your downconverter directly to the feed with no signal line loss. Extremely efficient, this antennas design includes many advantages over other dishes. I have current stock and most orders ship the same or next business day. The 3' N3IYR dish outperforms any other commercially available AO-40 antenna. Please visit my web site and look my antenna over. Leave me a comment if you like, or ask any questions you might have.

May I suggest that you go back and really read what Walt said? Looks to me like you actually missed the message.
To you any loss may be significant. To me it is not if it allows me to complete the desired communications and I know enough about my system to understand what loss I might be incurring and where to improve things if needed. Does it really matter if my coax loses 25 of my hundred watts? Depends. Most of the time it does not. I'd venture to day that over the years a great many hams have had such levels of loss without realizing it.

So what *does* it matter to a ham whether the feedline loss is one watt or 25 if he's running 100 watts? Actually none at all, except that some folks like to pick lots of nits. Seems to be a fixation of some engineers. 75 watts, or even 50, will be heard on the other end virtually always as well as the 100 if one was using a lossless line. But that doesn't stop the purists from discouaging new hams from ever getting on the air in the first place, where they could actually begin to learn how all this works. For many years I avoided using tuners because I didn't understand all this. Walt Maxwell took care of that.

> You can't skip over all these details, because they make all the
> difference between losses that are trivial, or losses that are large
> enough to put a 100W transmitter into the QRP league (and put a QRP
> transmitter into the noise).

Nonsense! If I'd had advisors like you when I was a 14 year old just beginning to try to get on the air, I'd have never even started. Fortunately I had practical minded folk like W0CTB who was licensed in

the 20's and grew up with radio to help me along. I guess this is just a different age, the age of perfectionism.
ANY coax of ANY length that any ham is likely to acquire and install won't cause such a drastic loss at ANY HF frequency with any load any ham is likely to try to use. We can write volumnous posts on the subject to make it all quite clear but no one would read them, and if a ham knows enough to ask that sort of question one can assume some minimal level of knowledge is present. I'm surprised you would attempt to make such a sensational case of it.

Such stuff is way beneath yor usually exemplary writings, Ian.

> Radio hams so often crave a single, simple answer - but here there isn't
> one. You have to work out what the numbers mean for your particular
> situation.

Ian, by that statement you demonstrate that you are in fact a purist and not a ham. If hams had to calculate exact feedline loss to get on the air there'd be damn few hams ever radiate a signal. If you wish to do so, fine. But don't try to tell me I have to know exactly what my feedline loss is, when I can be sure it's not grossly excessive by knowing what I'm using. Don't try to tell Walt Maxwell, either.

Would you suggest that the many times I and many others have huing a tempoprary dipole fed with whatever coax was at hand and just tuned it to good on-the-air success were just some sort of a fluke?

There's engineering practice and there's amateur practice. One can't say they SHOULD be different, just that most of the time they are. Unavoidably. Not many hams have the technical education to pursue their hobby as engineers, nor is there any realistic need for them to have, in order for them to have very satisfying success as active on-the-air hams. I think guys like you often lose your perspective over the years.

So Ian, you go right ahead and make it as complex a problem as you wish. The man asked a simple question, and I gave him a simple answer. Which was NOT incorrect.

Dick W0EX

Another point in the form of a "what if". What if you find yourself in a situation where you really need to get an HF rig on the air. You have a rig and power for it, but no antenna nor feedline.

What to do? Wring your hands and wish for the Coax Fairy to pay you a visit? Not me. I'd be grabbing the 6 or 8 feet of lamp cord off every appliance I could get my hands on, striping the insulation off the ends of the wires and twisting them together, making sure none could short. Any way available to get the length needed to feed the dipole I make of whatever wire I can come up with - copper if I can find it, even steel fence wire if it's all that's available.
"Twisted pair" lamp cord was a common feedline in the early days. It still works just as well now, probably better because of better quality insulation.

No coax connector to screw it onto the rig? No problem, just jam one of the wires into the center pin receptacle with a toothpick or small piece of wood, whatever, and attach the other wire to the chassis however you can. Use your imagination.

And soon I'll be on the air radiating an effective if perhaps attenuated signal, not sitting scratching my head trying to figure out the next move. Because I know this will work. And there would be no way I could know what my feedline loss is.

And I probably wouldn't even notice if I had no tuner to use on it if I measured the dipole elements with any kind of care. I know that my "wingspread" fingertip-to-fingertip is near-exactly 6 feet, so from that I won't even need a rule or measuring device to make the dipole.

If people take all the engineerese *too* seriously, they wouldn't even give such an installation a thought. And they'll be off the air.

Dick

Are you smoking wacky-tabaky?

As an example of the error in the above statement, consider a 80
dipole when operated on 40 meters. That antenna will have the feed
point impedance around R1900 J-2700 (Ref: NEC calculations) resulting
in a SWR at the feed point of about 119:1. If this antenna was feed
with 100 feet of RG-213 the additional loss attributable to SWR would
be over 7 dB. Maybe 7dB isn't considered drastic by your standards,
but most hams would feel it is.

Danny,
K6MHE

Reg, G4FGQ wrote:
"Don`t you think it would be a good idea to introduce a few numbers?"

Numbers may induce numbness. Doesn`t Reg have the programs that crank out the numbers effortlessly?

In "Radio-Electronic Transmission Fundamentals", B. Whitfield Griffith, Jr. gives a formula for average characteristic impedance of a dipole based on average space between the dipole wires and the diameter of the wires. Space between the dipole wires is called "S" and in the usual dipole is one-half the over-all length of the antenna. The diameter of the conductor is "d". The average "Zo" is :
Zo = 120(ln 4S / d -1) ohms.
Griffith calls the over-all length of the antenna "L", and this is equal to 2S.

Using the formula, Griffith gives a table of L/d vs. avg, Zo:
100 516 ohms
1000 792 ohms
10000 1070 ohms
100000 1342 ohms

Next, Griffith gives a formula for approximate dipole drivepoint impedance at first resonance using the average dipole Zo.

Approximately, the drivepoint resistance "R1" is given by:
R1 = 10ln Zo
where Zo is the average for the dipole.

Griffith also gives a table of first and second resonant lengths for three average dipole characteristic impedances:
500 ohms, 0.464 0.860
750 ohms, 0.474 0.924
1000 ohms, 0.484 0.950
The decimal fractions are in terms of wavelength. Smaller L/d produces a smaller average Zo. That is, a fatter wire produces a lower Zo, and a fatter wire produces a shorter antenna at resonance.

Griffith has an observation which may relate to broadbanding. He says current phase can shift from plus to minus in the antenna wire without magnitude ever becoming zero.

Terman says a doublet composed of two wires instead of one, lowers the reactive component of the antenna impedance. That implies a faster drop in reactance than in radiation resistance and thus a lower Q when replacing one wire with two in the doublet.

Best regards, Richard Harrison, KB5WZI

>ham is likely to try to use.

That just ain't so, so all the rest of that message (including the personal attacks) is worthless.

Take 30m (100ft) of RG213 - good, thick "low-loss" cable by HF standards. Matched loss is 0.2dB at 1.8MHz, rising to 1.0dB at 29MHz. Completely trivial, everyone agrees.

Increase the SWR to 2, and the extra loss due to the mismatch is 0.05-0.19dB across the same frequency range. Still trivial. *That* is what Maxwell was saying: if the SWR on your coax is already quite low, you don't need to sweat about getting it any closer to 1.0. Your line loss won't improve worth a darn.

But now increase the SWR to 20 - that's a feed impedance of only 1kohm, quite easily reached in a wire antenna that's way off resonance. Now the extra loss has risen to 1.5-4.1dB. You're still OK on 1.8MHz, but on 29MHz your total feeder loss is now over 5dB - that means 60% of your transmitted power is simply going to heat up the coax. Starting to worry yet?

If you try to operate a coax-fed wire antenna dead on its second harmonic, the mismatch loss at 29MHz can easily climb over 10dB - only 10% of your transmitter power reaches the antenna.

That's with good low-loss coax like RG213. If you try the same with RG58, you'll reach the same losses with a shorter length of coax, at a lower SWR, or at a lower frequency.

Also note that the SWRs I'm quoting are at the antenna. When the line losses start to rise, you see an optimistically low SWR in the shack.

>The man asked a simple question, and I gave him a simple answer.
>Which was NOT incorrect.

He'll get out fine at the edges of the band his antenna is designed for. That's not in dispute.

But he's also wondering about using the same coax-fed antenna on bands far away from its design frequency. If his tuner in the shack can match it, then for sure he'll get out and work people... but eventually he'll wonder why he doesn't get out as well as his friend in the next town... why stations calling CQ seem to go back to other people... why he has to

wait in pileups for DX that he really wants to work.

Eventually he'll be disappointed and he won't know why. The sad irony is, the more he cares about doing well in ham radio, the more disappointed and puzzled he will be.

That matters to me. I believe that we radio hams are *smart* people - we can handle a lot more than the dumbed-down half-truths that some people would feed us. They're selling us way short.

(FYI, I'm not an engineer of any kind. I learn some things about ham radio from engineers - they know stuff, and are worth listening to - but some of the most important parts of my ham radio education came from a hotel keeper, a variety of people who worked in shops/stores and offices, a pig farmer, a corn merchant, and a guy who left school at 16 and chopped meat for a living. Time and again, ham radio proves that if we're interested enough to *want* to find out about something, then we're also smart enough to handle it.)

Of course I don't expect everyone to calculate their feedline losses - there's no need. But I do believe that everyone who reads this can handle *two* simple facts about losses and SWR on coax:

1. If the SWR on your coax is already quite low, you don't need to sweat about getting it any closer to 1.0 (that's what Maxwell said).

2. But... if you make too many compromises with high SWR, long lengths and the quality of coax, losses can creep up on you.

The rest of the information is there, but only if you decide you need and want it. After all, it's a hobby.

Noooooo, Danny I'm not smoking wacky or any other kind. If a fella who holds a ham radio license doesn't know better than to try to use a coax-fed 80 meter dipole on 40 then it's time he learned, the hard way if necessary. The easy way out is to just parallel a 40 meter dipole with the 80.

The main reason MF and LF broadcasting station antennas were built fat and sturdy was to prevent them falling down in bad weather. This turned out to be minor virtue - almost un-noticed bandwidth slightly increased.

To find the difference in bandwidth between a 7 MHz half-wave dipole constructed of 18 AWG and another constructed of 10 AWG, download program DIPCAGE1. Just enter 1 wire and its diameter.

You can also calculate bandwidth of a folded dipole with wires near or far apart. You can go up to 3 or 4 feet in dipole diameter by using a cylindrical wire cage with any number of wires in the cage.

Measure current with toroid sampler (current transformer)
Measure voltage with a resistive voltage divider
Measure phase by feeding current sample and voltage sample into a phase detector, such as the phase detector part of a PLL chip.

Lots of interesting work to make it accurate, but in concept this should work OK.

Hi Richard.

X/R is only an approximation of antenna Q if the Q is large (X >> R). At frequencies near resonance this approximation fall apart rather quickly.

An easy way to approximate the antenna Q at resonance is from the 1/2 power SWR bandwidth. The 1/2 power point is an SWR of 5.828. In determining SWR for a Q calculation, you cannot use the feedline Zo. You must use the antenna's resonant resistance for the SWR calculation (SWR at resonance will equal 1.0). Knowing the 1/2 power SWR bandwidth (BW), Q is found from 2 / BW.

Begging your most humble pardon, unless you and I have vastly
differing views of ham radio, it IS so.

The original question forced one to make some assumptions, and it's
clear we chose different ones. I assumed since he was using his tuner to
match to 1:1 that he had to be using it on a single band. You just can't
do that on all bands. I don't know what you assumed, obviously it was
something else.

I know that any ham who has learned enough to qualify for an HF license
should know that he can't use a single dipole at 52 ohms on all bands,
even with a tuner-but I also know that's a stretch with today's
memorize-me tests. I don't consider myself so different from other hams
that I wouldn't know (as Danny seemed to think) better than to try to
use a full wave coax-fed dipole, such as using an 80meter dipole on 40.
Of course that will result in unusably high reflection loss and make it
necessary to use high impedance balanced line and a balanced tuner (or
Cecil's scheme). I didn't glean from the inquiry that he was in the dark
on that point. So perhaps I should have said "single band" dipole and
assumed nothing. Mea culpa.

so all the rest of that message (including the
> personal attacks) is worthless.

Personal attack are usually worthless. Yours, too.

>
> Take 30m (100ft) of RG213 - good, thick "low-loss" cable by HF
> standards. Matched loss is 0.2dB at 1.8MHz, rising to 1.0dB at 29MHz.

Nope, not if I really need to use that system at that time. I will also know that the 40 remaining watts of the original hundred will be quite effective, particularly on 10 meters. Desirable? Not at all. Useable? Definitely. And no one should or would intentionally cause himself to fall into such a situation.
But it's unproductive to teach newcomers that high loss situations are always bad and never useable. It's also incorrect. That's the power of the knowledge and experience to sort it out.

> If you try to operate a coax-fed wire antenna dead on its second
> harmonic, the mismatch loss at 29MHz can easily climb over 10dB - only

>

But that won't be the case if you're using a dipole on a single band. That was the point. And that was how I understood his situation to be since he said he was using a tuner to obtain 1:1 match. I've never seen a dipole that could be matched to 1:1 on several bands with any tuner I ever tried. And I have tried. Two or three dipoles for different bands paralleled are another story. I use that scheme routinely on most all HF bands.

> That's not in dispute.

Then we have no dispute. I know he won't be able to use it on multiple bands. As I read his question, he was wondering if he should use ladderline in place of his tuner on his single band to get less loss. The answer is no.

>

Good grief, man, it he gets that far without realizing he has a serious problem he's too far out of his element to survive anyway. His gear will be either roasted or in foldback shutdown.

>

The operative term is "acceptably low". It's clear that term may mean different things to different people. I think it's wrong to insist that hams always have to have only a low loss antenna system when sometimes even considerably lossy antenna systems is very much acceptable and when under some circumstances their availability and use can be critical.

> 2. But... if you make too many compromises with high SWR, long lengths
> and the quality of coax, losses can creep up on you.
>

Sure can. That doesn't mean it's necessarily all bad to have increased losses- especially in ham radio where the usual case is not marginal communications and QRP is a way of life for many anyway. If 5 watts will serve much of the time, it really doesn't make it a felony to lose even half of a hundred watt signal at unusual times, does it? It's a full 10

dB above QRP and only 3dB down from the original. Unusable? Not at all. Match it and go.

It does mean it's important to realize how this works and to be able to evaluate ones situation to make the determination whether or not your system is usable in a given situation. And to be able to make the proper corrections to make it more efficient, if that can be accomplished under the existing circumstances. THAT is partly what I learned from Walt Maxwell. Since I began ham radio some time before I learned enough to make such evaluations I can now appreciate just how compromised some of my early ham radio antenna systems must have been, and that of many other hams. But they still worked well and I made lots of contacts. There surely is a message in that, for some of us at least. Optimal is best, but not mandatory nor even necessarily desirable at all times. Circumstances and situations dictate. Many hams with antennas who live in areas with deed restrictions will agree.

The term "well" is very subjective, of course. To me it means doing the job acceptably given the instant circumstances. I see a lot of perfectionism from many quarters today that it seems may cause some new hams the serious problem of believing that simple, directly constructed but flexible antenna systems won't work, or won't work well enough to use on the air. It simply isn't so, and for as long as I'm able I'll counter that concept regardless of who is is that puts it forth.

Many if not most ham radio antennas are far more inefficient that most of their owners believe. Most have been spoonfed data that are incorrect enough for their individual installation that they believe they have efficiencies and attributes that are simply not present.

> The rest of the information is there, but only if you decide you need
> and want it. After all, it's a hobby.
>

There isn't a single thing you've written above that I didn't know other than your personal background. I answered the poster's inquiry as I read it, and it's clear that you and I read it quite differently. You seemed to attack my answer as grossly incorrect when it was indeed correct for the question as I read it. If I'd known I'd wind up in a big controversy over such a seemingly simple topic I probably would have just refrained from answering, but I see far too many answers to that sort of question that simply do not answer the question.
Seems usenet is becoming nothing more than an acrimonious feuding ground, even the the more technical groups. Sad.

==========

I expect the military popularised it - brute force and ignorance as usual !

It would have been more discreet merely to use resistance wire in the
antenna.

Excellent! Well done Roy.

Had a radio amateur friend who built an 80 meter vertical beam many years ago. The intent was to improve signal into a net, not for DX. As I recall, the reflector wire was about 10 meters above ground with the driven element another 10 meters higher and a director at about 30 meters above ground. At least over a 200 to 300 mile path, it was a stomping antenna.

Yep - and they cost a pretty penny too.

The X-ray showed a toroid transformer and a circuit board, too.

QST opened one up and found it full of epoxy. They dissolved the epoxy layer by layer and found that the circuit board served no electrical function - it wasn't connected to anyhting, and was in fact an old computer board that had been cut down to fit inside the box. Dissolving more epoxy showed that the balun was indeed functional, as were the noninductive resistors at the very bottom of the box.

Why the toroid? Because without it, you'd be able to measure 50 ohms DC resistance across the input and output terminals. The toroid looks like a short to DC.

The "Match-All" folks can't even spell "balun" correctly - or perhaps that is intentional. As pointed out, "latest Maxcom technology" is a dead giveaway. Note that the device has a "maximum temperature rise" of 80 degrees F! Note also the caution not to be concerned about received signals being several S-units less.

Don't waste your money.

It doesn't match any antenna, it matches the rig. What RF it radiates
is incidental, and surprisingly there is enough radiated to work
stations, some with useful signal strength.
Just goes to show that a very poor radiator is much better than none at
all. Otherwise they could never have sold any of these abominable
things.

You never heard of multiple resonances? They're not uncommon.

706. G5RV on Roof--Need Some Suggestions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-13 02:20:21 UTC
From: Mike <"scifiguy at starband dot net">
Message-ID: <d9khqucu7u0tmh5jstmrq927h1p79vmt68@4ax.com>
Source record: 133095

Living in a home owners association, I have few options for a good stealth HF antenna, but I think I've found a reasonable compromise. I decided to mount a G5RV dipole on my roof, with the center supported by a non metallic rod at the chimney, and the tips held several inches off the roof by non metallic brackets attached to the eves. This would make it somewhere between a flat dipole and a shallow inverted V. Since my nearest neighbor is about 800 feet away, I doubt anyone will be able to see the wire. The implementation seems pretty simple, but I need some advice:

Is it okay to lay the 300 ohm twin lead coming off the antenna on the roof tiles? Since the tiles are made of concrete, it is very difficult to mount standoffs, but I guess I could if I had to.

The chimney is modern construction--wood frame, with stucco over wire mesh, aluminum duct down the center, and an aluminum rain guard on top. With all that aluminum, what is the closest I should allow the center portion of the antenna? The mount will be off the side of the chimney to avoid soot build up.

Needless to say, I will be installing a lightening arrestor where the coax enters the house. Is there any more I should do to protect my home from lightning strikes (I live on a peak, and my chimney is the highest point for about a quarter mile)?

Thanks in advance for suggestions.

707. Re: Measuring voltage, current and phase at VLF Ae feedpoint

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-13 02:31:54 UTC
From: k7itm@aol.com
Message-ID: <3200347.0210121831.f54a821@posting.google.com>
Source record: 133096

As Jack said and Cecil intimated, sample the current and the voltage...perhaps the current with a toroid current transformer, and perhaps the voltage with a divider (resistive or capacitive) or a voltage transformer.

To turn the voltage and current samples into signals you can deal with relatively easily...if you can generate a clock at 4 times the operating frequency, you can then implement something like the Tayloe mixer, and get in-phase and quadrature values for the voltage and the current. From those, it's not difficult to find the phase angles...it's fairly easy trigonometry. The difference between the voltate and the current phase angles should give you the load phase angle.

I would suggest they spend some time calibrating the system. Don't just assume it will be correct, but test it with known loads. With reasonable construction, I'd expect it to be pretty accurate by design, but they won't know till they test it.

Cheers,
Tom

I was not responding to Ian's comments just yours. ie.." ANY length at
ANY HF frequency at ANY load" . Furthermore what may be "likely" to
one person can be some altogether different to someone else as it is
not specific. However, " ANY length at ANY HF frequency at ANY load"
is quite specific.

I have copies of Walter's book. So can please tell me where it is in
his book that he states that "ANY coax of ANY length that any ham is
likely to acquire and install won't cause such a drastic loss at ANY
HF frequency with any load any ham is likely to try to use."? Because
I sure can't find it.

And, yes can you do it with out name calling and personal attacks?

710. Multiband Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-13 02:49:10 UTC
From: Ken N4VSD <REMOVECAPSn4vsd@yahoo.com>
Message-ID: <Ga5q9.53367$VQ2.12372830@twister.midsouth.rr.com>
Source record: 133097

Hello all,

Anyone know where I can find the formulae for building a multiband dipole using several dipoles connected to the same feedpoint? Gets a little complicated when building an antenna for six different frequencies between 4.5 and 18MHz. Pruning would be a lot easier if you have an approximate length for each dipole. I remember seeing an article in QST several years ago.

Thanks,

Ken

That's the crux of the whole thing. You can basically load
anything
without regard to efficiency or radiation patterns and all
that sort
of thing and still have a great time on the air. There are
many
people working low power and QRP (I myself work 10W or less
most of
the time) having a great time while others are sitting back
and
fretting because something about their system is not ideal.

It would be nice to have the physical realms required to be
able
to run perfect or nearly so systems, but I would venture to
say
that the majority of hams cannot. For them, the fun is
being on
the air. Yes, perhaps ignorance is bliss, and getting on
the air
regardless of other limiting factors is where the fun is.

I love playing with antennas, but I cannot let those factors which are beyond my power (through knowledge, physical, or financial limitations) spoil the fun that is otherwise available.

No! I wouldn't use the Maxcomm or variants thereof, but many have succumbed to the sales pitch and are on the air having a
great time.

Ham Radio is fun! For some it's the technical side, for others, the operating. Have a great time regardless!

That's my 2 cent rant!

Hello Wes

Why would you want an operating system that doesn't work
with half of your software, especially if your system is stable
now? If it ain't broke, don't fix it!

Can you say "context"? Do you always jump in right in the middle of thread and hold the current poster responsible for reciting the entire thread in each and ever segment/post? I can't see how you can answer that question in the negative, given the above. Should you have actually read the entire thread, as Ian apparently also did not, it would have been quite clear that the reference was to a single band. If a licensed ham has not gained the basic knowledge to cut the dipole to fit a single band then he can and LIKELY will remain confused whatever help he is offered by anyone.

And yes, Dan, unfortunately and strictly on your own, you're showing all too many of the characteristics of a horses ass. It was disappointing to see Ian go off on such a wild rant without actually reading what was written. You seem bent on joining him. Feel free, but don't expect to bulldoze your way over me in the process as Ian evidently thought he could. I had a lot of respect for him before that. I'm afraid he made a big dent in it.

That's because that statement is not to be found in his book. But within the context of this thread and my participation in it, it's true.

I bought a stereo that (surprise) actually has a functional plug in for an external AM antenna...something I thought all manufacturers had given up on. It was supplied with a small plastic loop bound wire am antenna to use which is ok, but I want a stand alone vertical am antenna so it need not be adjusted for direction. Any advice?

Ken,
Just like any other 1/2 wave dipole, (468 / f) for the length
of each. You'll have to do some tweaking because every
installation
is different, none are simple 'cut' and hang them up unless you're
very, very lucky.

Source record: 133111

this is common on most antennas. with an inverted L you would see the 'best' swr dip where the vertical part is 1/4 wave long. at this frequency the real part of the impedance is in the range of about 30-70 ohms or so which provides a good match for the common 50 ohm coax.

as you go higher in frequency the impedance typically goes higher until you get to double the frequency where the vertical part is 1/2 wave long, after that the impedance typically comes back down to another minimum when you get to the frequency where the vertical is about 3/4 waves long. this dip typically won't be as deep as the first one because the real part of the impedance is probably not near 50 ohms... so while the antenna is 'resonant' it is not 'matched' to the feedline so the swr at the resonant point is not 1:1.

there can also be other dips caused by coupling to nearby conductive objects. resonances in rain gutters, other antennas, power lines, fences, etc can all cause dips in the swr of an antenna.

"Any advice?"

A radio needs to pick up only enough signal to overcome internal noise..
For AM broadcasts, the height of the vertical antenna tends to determine
the received antenna voltage because the signal is vertically
polarized..
15 to 20 feet is usually plenty of antenna.

Best regards, Richard Harroison, KB5WZI

StarGazer wrote:
"Heard of them (harmonics) but they aren`t deeply nulled like the first one (resonance)."

At first resonance, radiation resistance of a dipole (at a current loop) may be 72 ohms. The second resonance radiation resistance may be 200 ohms. The third may be 102 ohms. The fourth may be 260 ohms.

SWR determinations are usually affected by inpedance.

Best regards, Richard Harrison, KB5WZI

726. QRM entering via the antenna connector ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-13 12:52:39 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210130452.15c3ffca@posting.google.com>
Source record: 133114

Hi,

As some of you know it, I 'm using a sloper longwire made of simple electrical wire (for the part located outdoors + RG58U indoor) for SWL purposes in my LX appartment. One half of the wire, the RG58U, is connected to the antenna input of my RTX using a "banana" jack (sort of phone jack with only one pole) that enters in the middle of the female PL connector attached to the RTX. This connexion is quick and easy to un/plug.

As I experiment much QRM, over 57-9 on all bands over 10 Mhz I suspect a local generator to create these noises (as noises disappear 10m away from the house) that i capture with this antenna system (10m running indoor, 15m running tilted outdoors).

Here is my idea:
I am currently replacing this wire by a windom of about 25 m long constituted of isolated wire and a balun ending with a PL female connector I will connect to a coax RG58U, this last running indoor over 10m at ceiling level to the RTX antenna input jack.
The shorter part of the windom (about 8m long ?) will run either in only one room at ceiling level or will be tied accross the appartment, to test.
The balun will be placed just out of the window, the longer segment running outdoors and tilted as a sloper to the end of the garden over 15m, attached with an insulator to a fence.

Why this change ? Looking accuretaly the windom and comparing it with the longwire, at first sight both antennas are nealy "similar" in design, excepting.... i have noted that the windom uses a balun (I ignore it for this explanation), an isolated wire (covered with plastic), a PL connector and is insulated at each end. The wire itself is ticker.

So I suspect that one noise "catcher" is my longwire itself and its ordinary design : the wire is not isolated at all and I use a banaba jack RTX side.
I suspect various things:
- the banana should capture much more QRM than a PL-259 and
- the isolated wire could probably help me in removing most of the noise I currently capture with the indoor part of the wire.

Should the idea to replace the longwire by an isolated windom with PL a good one ? In all cases I will test it next days and I will complete this mail.

I bet this windom could remove a lot of QRM due to its design, not all
but to say maybe 3-4 points of the S-meter... You bet ?

Even if you use coax for the indoor portion of the run, noise can couple to the outside of the braid, and travel back to the antenna wire in common mode fashion.

What kind of balun are you using on the longwire? A 9:1 for impedance matching, or a choke balun to reduce common mode coupling? I'd suggest using a common mode ferrite choke on the coax before it enters the building. Ditto for the Windom. You will need to decouple the coax where it exits the building, or all of the noise picked up on the braid will couple back to the antenna.

Pete

The dielectric losses will be higher especially when it rains.
Question is: How much loss are you willing to tolerate?

I have my G5RV mounted similar to this and have decent results;
however, If possible, the twin lead needs to come off the other
elements at 90 degrees and should be straight out. That section will
radiate esp. on 40 and 80 meters. I cannot tune 40 on mine with the
rigs internal tuner and even using an external tuner I have some
trouble with that band. 6-80 no probs other than than. I couldn't get
mine up high enough to extend the ends, so I wrapped around the eves
using electric fence stand offs to keep the wire away from the house.

Wouldn't a quarter-wavelength be better? :-)

It's a balanced dipole fed with balanced twinlead. Assuming a properly
functioning balun at the coax/twinlead junction, why will the twinlead
radiate?

I actually did that once. I put a length of zip cord on a light bulb.
Taped it to a broomstick. Put it outside my bedroom window. Hooked it to
my Knight-kit T-50 transmitter and actually worked people on it. j

My best DX was from NE Ohio to NY state on 40cw.

Yeah, a quarter wave would be better, but at the low end of the broadxast band that is over 300 feet. You would need a balloon or something to hold up the end. I don't have a BC antenna as such, but found the 75 meter antenna works best. Polarization does not matter for skywave signals. Unless you have a receiver with really good selectivity and dynamic range, putting up a big antenna could just make things worse. With an ICOM 756 and 75 m antenna I can pull in stations from 600 miles away that are 10 KHz from local 50 KW stations. Works best when I switch to SSB and tune the for the sideband that is further from the local station.

Ken,

I did exactly that on 18, 24 and 7 MHz ham bands. What I found out the hard way is that you have to TUNE THE LOWEST FREQUENCY ANTENNA FIRST; the highest frequency last. I had the ends of the 24 MHz antenna about 6 feet below the 18. The 7 MHz was rotated about 15 degrees with respect to the others. SWR at resoance was below 1.5:1. A 1:1 balun was used.

If at all possible, run an EZNEC simulation on it.

CAM, W5DXP wrote:
"Wouldn`t a quarter-wavelength be better?"

To transmit, yes. To receive, probably not.

FCC rules specify minimum field intensities stations must proovide to intended service areas.

In urban business and industrial areas, the rules say 10 to 50 mV/m is needed.

In city residential areas, 1 to 10 mV/m is specified.

In rural areas in the winter months, 0.1 to 0.5mV/m is specified.

In southern rural areas of the USA in the summer, FCC specifies 0.25 to 1.0 mV/m. Lots of "static" under these conditions.

At 1 mile from a 1 KW broadcast station, something just under 200 mV/m is received. At 20 miles, about 10 mV/m is usually received, if sea water surface separates you from the station.

A 20-foot vertical antenna is about 6 meters and capable of 6x10 mV/m at 20 miles from the 1 KW station.. 60 mV/m exceeds FCC requirements for noisy urban areas. The irony is that more antenna picks up more noise along with the increased signal and the S/N remains about the same. The minimum specified signals exceed receiver internal noise.

A directional antenna such as a loop can improve S/N by rejecting some of the noise from undesired reception directions.

Best regards, Richard Harrison, KB5WZI

Hi Ken,

As long as the dipoles are not harmonics, you should be able to use the
quarter wavelengths. If the sides of the dipoles are in the same plane,
there will be some interaction, but you can adjust with an antenna analyzer.
If the elements are 90 deg. apart, there is less interaction.

Good Luck,

Bill, W4WNT

Hi Josh,

Sounds like the 4:1 balun in the tuner is the problem. Make up a 4:1 balun separately from the internal one and run it to the coax connection to see if that solves the problem. The Wireman has kits for all sorts of baluns.

I'd also check all solder connections as a precaution, but if the QRP tuner works, that points to the MFJ as the source of the problem.

Good Luck,

Bill, W4WNT

Source record: 133133

Hi Doc,

I haven't seen them in person, nor have I used them, so I only know what I have read on the internet. From what I have read, here are some differences...

Antenna's and More G5RV: Weather sealed center portion, where the feedline connects to the horizontals. 30 foot 300 ohm twinlead feedline, with a PL-259 connector at the end. All mat black.

Van Gorden G5RV: The horizontals are natural copper color (according to the photograph on eHam--looks like either bare wire or clear insulation). The feed line is 17 feet of 300 ohm twinlead. They include 100 ft. of RG-8X to attach to the twinlead (using your own balun).

Both get good reviews.

I am leaning toward the Antennas and More version, because it might be stealthier over my roof, and I think I can manage to run the 30 foot twinlead all the way to my transceiver. I just don't know if there are any performance or quality differences that would recommend one over the other.

Neoklis wrote:
"---the measurement of voltage, current and phase angle at the feedpoint of a VLF antenna with digital indication."

A vertically polarized antenna is required for VLF. Current indication is given by a thermoelectric ammeter at the feedpoint. Since the antenna impedance has been measured, a current indication is usually sufficient information. A digital voltmeter can be used to read the d-c output of the ammeter`s thermoelectric unit or the output of a similar unit and this can be calibrated to agree with the scale of the thermal ammeter.

A good a-c digital volt meter will read a VLF voltage across the base insulator without serious problems. The meter may have an output for remote indication.

For phase between voltage and current, sample the voltage through a coupling capacitor. Sample the current through a current transformer. The voltage drop across a section of the ground connection could also be used as a current sample for phase measurement.

The voltage and current samples are applied to inputs of a chip designed to produce an output proportional to the phase difference between the two inputs. It`s a phase detector chip. A digital voltmeter can again be used to produce the digital output if the chip doesn`t.

I recall seeing a circuit from a Signetics applications note reproduced in a Graf and Sheets demodulators book and also in the second volume of their "Encyclopedia of Electronic Circuits". Its output was d-c proportional to the phase difference, but the digital meter`s output could again be used for the student`s requirements.

Thierry,

I think when you say QRM, you mean QRN (noise). From your description it seems that the shield of the coax is not connected to your radio. This makes the RG58 moot, and it acts like a single wire. If you replace the banana plug with a proper connector that connects to the shield of the RG58, you should be able to eliminate some of the in-building noise that you are picking up. If your radio has a single pin antenna jack, connect the shield of the coax to the ground connector on your radio. Any balun should be at the outdoor end of the coax.

Hi Richard,

I recognize the source of your numbers, but they don't seem to scale
to actual copper in the air in direct correlation to the term employed
(volts/meter). I put EZNEC to work (perhaps incorrectly) to the
following results. I note nowhere the same literal correlation seen
by a load (receiver) consistent with your statements above, except by
the degree change of 1 mile to 20 miles.

[As an aside, I would note that even though the "sniffer" antenna is
out about 5 wavelengths (at one mile), that the effects of its size
and load will be cast back into the main antenna and its source
(albeit in the decimal places).]

scenario:
ï¿½ wave vertical above 120 ï¿½ wave radials one meter above
real/high accuracy ground;

first antenna excited with 195.5V (1000W on the nose)
at 1000KHz (300M);

second user antenna, located at 1 mile, vertical dipole,
bottom tip one meter above same ground;

second antenna load of 1 KOhm representing one of two
applications:
1. xtal receiver tuned circuit, hi-Z headphones, and diode

2. diode and metering circuit load

for a 1M tall user antenna, the load sees 317ï¿½V
for a 20 foot (6M) tall user antenna, the load sees 8.98mV
for a 10M tall user antenna, the load sees 23.6mV
for a 20M tall user antenna, the load sees 88.4mV
for a 50M tall user antenna, the load sees 553mV
for a 100M tall user antenna, the load sees 3.16V
for a 150M tall user antenna, the load sees 10.35V
for a 200M tall user antenna, the load sees 6.88V

Move the vertical dipole out to the 20 mile mark.

for a 1M tall user antenna, the load sees 3.78ï¿½V
for a 20 foot (6M) tall user antenna, the load sees 107ï¿½V
for a 10M tall user antenna, the load sees 281ï¿½V
for a 20M tall user antenna, the load sees 1.06mV
for a 50M tall user antenna, the load sees 6.58mV
for a 100M tall user antenna, the load sees 37.4mV
for a 150M tall user antenna, the load sees 121.4Mv
for a 200M tall user antenna, the load sees 79.6mV

Thierry,
If I understand your description correctly, the RG-58
coaxial cable is serving no purpose with your 'slopper'
antenna, since the shield of the cable is not connected
to the radio. It is acting the same as if it were replaced
with the same wire used for the antenna. You are, in effect,
using a random length wire in the 'shape' of a slopper.
The insulation of the wire contributes no protection from
noise. It does prevent contact and possibly 'shorting' the
antenna to objects around it that may touch it.
Before changing to the windom antenna try this. Connect
a counterpoise to the outer , threaded, part of the 'PL'
connector on your radio. This 'counterpoise' should be about
a 1/4 wave length long for the frequency you wish to listen to.
(The length is not critical if you do not use it for
transmitting.)
Lay it on the floor of your apartment in almost any configuration,
but not coiled up. See if it makes any difference in the signals
you are hearing. This counterpoise wire acts as a 'ground', or
the 'other half' of the antenna. If reception is improved, you
may not have to put up the windom antenna. If reception is not
improved, then you always have the option of the windom antenna.
The closer your antenna to noise sources, the more noise you
will hear. Having any part of the antenna in-doors is not as
good as having all parts of the antenna out-doors, and away from
the man-made noise sources of a building. That's true even if the
antenna is shorter than it should be (to some extent).
Good luck. I am interested in how the two antennas compare,
and will watch for your next post...

From: 'Doc <w5lz@cwis.net>
Message-ID: <3DA9D86D.84879B61@cwis.net>
Source record: 133140

Mike,
I haven't used either one so take this for what it's worth.
It sounds like the electrical properties of both antennas are
approximately the same, so performance should also be about the
same. Construction techniques are important to an extent, but
I think they don't matter much between the two.
If I had to choose between the two, I think price would be
the determining factor. A G5RV antenna was never meant to be
'near' surrounding objects, and those surrounding objects will
affect it's electrical properties. It's impedance will be
different than if it were hung in the clear, and it may not be
even 'close' to what you want if it's erected as you plan. The
only way I know of to see how far 'off' the antenna will be is to
put it up and try it (too many variables to try to compute it).
(If it were easy, it wouldn't be any fun, would it?) I would be
interested in hearing how it turns out.
Good luck...

The Kirk antennas were a disaster as far as mechanical design. A little ice and they all came down. He died before his customers could take him to court.

The 3 element 40, 5 element 20, and ? element 15 did work electronically. The moral is that antennas are both mechanical and EM devices.

Peter,

Maybe you want to tell us what you are trying to do. I had jumped to the conclusion that you were interested in stations far away. A HiFi radio is probably the worst possible choice for that, because it is designed to have good fidelity, not good selectivity. The two are opposites. For local stations, the loop antenna that came with it has a lot going for it.

Well, the B&W actually works, and is based upon sound antenna theory. Check into the "T2FD" (tilted terminated folded dipole) for an explanation on how it works.

Up high and in the clear, the B&W 1.8-30 works well on 40-10, and everywhere in between. It actually shows some gain over a dipole at 20 and above, since the entire antenna radiates. (Close to 200 feet of Copperweld in the air...) Passable on 80, and some have said it's a decent receive antenna on 160 when mounted as a sloper. (If interested, see: http://www.eham.net/reviews/detail/1016)

But as for the Matchall, it's definitely a "P.T. Barnum device".

Richard Clark, KB7QHC wrote:
"I recognize the source of your numbers, but they don`t seem to scale to actual copper in the air in direct correlation to the term employed (volts / meter)."

I said: ---"something less than 200 mV/m at one mile from a 1 KW broadcast station is received. At 20 miles this is 10 mV/m."

The above came off the top of my head. The number in my mind was and is 196 mV/m for radiation from a 1/4-wave radiator. Don`t know where it came from. It`s been in there too long.

I`ve now gone to the books, starting with the 2nd edition of Terman`s "Radio Engineering" from 1937. Sure enough, on page 597 is Fig. 333 for strength of ground wave as a function of distance and the first chart confirms my statement. Indeed, something just under 200 mV/m is the strength at one mile.

Griffith confirms my number too in Fig. 42-2 on page 346 of "Radio-Electronic Transmission Fundamentals". He also has a 1/2-wave radiator represented on the same figure which lays out just under 250 mV/m at one mile for 1 KW input to the antenna. On page 347, Griffith says: "---the field intensity at 1 mile rises (vs, a short radiator`s 186 mV/m at one mile) to 196 mV/m when the tower is 1/4 wvelength high---."
Hey! that`s my number. I`m certain my memory was accurate this time.

As for the strength at 10 miles, it is simply the strength at 1 mile divided by 10. The volts per meter decline linearly with distance. It`s the power in the wave cross section that declines by the square of the distance. At 10 miles the power in the wave is 1/100 if the volts are 1/10. This ain`t rocket science, as they say.

The rule is that if you optimally place a 1-meter wire in the field, the volts induced in it equal the field strength in volts per meter. Half the power in the wire is re-radiated if the wire`s radiation resistance sees a matched load. 50%. That`s the most a load can get from the wire. Any other load will cause more of the power to be re-radiated. A no-load on the wire will cause 100% re-radiation.

But as long as the vertical receiving antenna is a very small fraction of a wavelength, the voltage generated by r-f sweeping across it is proportional to its length. Six times the length of wire produces nearly six times the voltage.

I tried to cover the earth loss versus the inverse distance decline by specifying sea water as the ground wave path. That works at 10 miles

according to a check of the propagation curves.

Broadcast band wavelengths in the USA are as long as 545.45 meters, or 0.339 miles. As long as you have more than 2 wavelengths or more separation between vertical antennas, they have nearly negligible mutual impedance. One caveat is an extraordinarily large antenna array. In the case of a 1/4-wave radiator at a mile`s distance, this is no problem.

I was not trying to be precise because there are usually conditions to upset precision. Radial field measurements are made at many distances for this reason.

I often err, but I don`t see any mistakes in the posting Richard Clark refers to.

Best regards, Richard Harrison, KB5WZI

Yep. A version of the "T2FD" - "Tilted, Terminated Folded Dipole". Originally
designed to be installed as a sloper and fed with 600 ohm line - circa 1947. It
was meant to be a nondirectional nonresonant RECEIVING antenna.

>They also mention not to be concerned about the lower received
>signals.....hmmmmmm.

'zactly.

Only thing they didn't say was how you can enjoy the challenge of QRPp with any
100 watt transceiver - by using their antenna.

Hi Richard,

No mistakes were pointed out. Rather, I performed a simple receive
antenna test at the specified distance from a classic AM transmission
scenario and nowhere in the model did the load ever exhibit 196 mV/M
characteristics - depending on what is meant by this "196 mV/M." Is
that meter of wavelength, meter of physical length, meter as a portion
of a quarterwave length antenna, or one meter absolute size antenna?

If you held your fantastic, magical RF Voltmeter probes one meter
apart, would you measure 196mV at a distance of 1 mile from the 1KW
source?

Richard Clark, KB7QHC wrote:
"If you hold your fantastic, magical RF Voltmeter probes one meter apart, would you measure 196 mV at a distance of 1 mile from the 1 KW source?"

If the probes were attached to the opposite ends of 1 meter of vertical wire without upsetting the interception of the wave, you should get about 196 millivolts if the earth loss is small and disturbances are insignificant.

Field intensity meters for AM broadcast work are usually a little different from those used for H-F field intensity measurements. H-F field meters are usually equipped with a specific dipole used at considerable height (25 or 30 ft) above the earth to avoid some of the ground effects on the measurement.

A medium-wave antenna couldn`t be elevated enough to make any difference in the measurement disturbances, due to the long wavelength. So, the measurement is made near ground level, and it is the ground wave that is of importance. The antenna used with a medium-wave field strength meter is usually a loop antenna, placed for vertical polarization. This is often built into the lid of the meter and removable if desired.

An internal calibration oscillator is usually included to trim the gain of the receiver / field strength meter so that its indication becomes a measurement.

The measurement man is often rechecking at prescribed locations chosen for few pitfalls. Otherwise, he needs to be sure he has found a suitable site and properly locates it on the map.

Best regards, Richard Harrison, KB5WZI

770. Re: Off resonance antenna and using coax???

Newsgroup: rec.radio.amateur.antenna

Stargazer, now that all the noise has subsided, and the trolls have
been shooed from this thread, I see that no one ever gave you a decent
answer to your questions. Allow me to me now give it a more complete
treatment:

StarGazer wrote:
>
> How far off resonance do you have to be before using coax
> will significantly affect the antenna system performance.
> I'm still using a tuner to get a 1:1 SWR.
>
> I have about 4:1 on the bottom of 80 m and tune it out with
> the tuner.
>

Within a single band, when you're using a single band dipole tuned at
the line input, there is nothing to be gained by changing to ladderline.
Your very minor loss from band edge to band edge while matching the
antenna to 1:1 with your tuner is insignificant, and changing it won't
save you anything of note. That was the message Walt Maxwell gave in his
book "Reflections". In fact Walt used that method when he designed the
antenna systems for some of the weather satellites.

> Also.... For 30 m what would be the best off resonance
> antenna... A 40 m dipole, 80 m dipole or an Inverted-L for
> 160 m.

That depends on what you want to do. Using an 80 meter dipole will give
you some gain in some directions, and a shallow null in others. If you
want best all around coverage I'd use a 40 meter dipole.

> I swear I see a shallow null around 10 MHz with the Inv-L???

Most antennas will have some resonances at various frequencies other
than their harmonics, but they usually aren't useful. But that one might
be. I'd try tuning the Inverted L to it and see how things load up. You
might have your 30 meter antenna requirements met already and it might
just work out for you on 30. Neither you nor I will know until you try
it.

You can also just parallel a 30 meter dipole with your 80 meter at the
feedpoint and tie it off wherever you can find, in whatever
configuration you can easily arrange. It will work fine.

From: cbhoelzel <n4bjx@naxs.com>
Message-ID: <3DAA2E46.F4368BB@naxs.com>
Source record: 133159

Has anyone taken two Hamsticks and mounted them horizontally with one fed by the center of the coax feedline and the other connected to the feedline braid?

How well have they worked for you, as compared to just one mounted vertically?

Thanks,
Chuck

I don't know of any standard formula in use for that purpose. I've used paralleled dipoles a lot, and usually cut them to the standard halfwave dipole formula. That will make them all a bit long since there's some added capacitive loading on each from the presence of the others - more pronounced on the shorter/higher frequency dipoles than the lower. But since I like slightly long antennas when using a tuner I don't worry about it and the autotuner in the Icom doesn't protest at all, just tunes them right up.

Dick

773. Re: How come there are shallow nulls with dipoles on other freqs??

Dick Carroll wrote:
'Wouldn`t that seem to mean the other resonances were at a frequency where the Q of the antenna was lower?"

That is probably a result of more wire length meaning less energy reflected back to the feedpoint. So, more energy is radiated and lost in heat and the disappearance of this energy increases resistance and lowers Q.

The antenna has a characteristic impedance determined by the L/d of its wire. This could be anything from just under 100 ohms to just under 1000 ohms. If there were no reflection from the far ends of the antenna, the antenna`s impedance would be based on its Zo. Instead, it`s based on the combination of incident and reflected waves in 1/2-wave dipoles.

A dipole many wavelengths long would have a high impedance like a rhombic of 600 ohms or so, and for the same reason. It would be based on the surge impedance of the antenna. Antennas with high resistance and low reactance, like the rhombic, have a low Q.
The downside of the long dipole would be its lousy pattern.

Best regards, Richard Harrison, KB5WZI

774. Re: TREES TREES TREES (Need insight)

Source record: 133165

Tim Groat wrote:
"Another point is, 100 KW transmitters can arc to the trees and set them on fire if you let any branches touch the antennas!"

The antennas were 1/2-wave above ground level, but just the 600-ohm transmission lines were hot enough. I calculate the peak voltage at 100% modulation (a frequent event with the audio compressors we used) at 21,900 volts. You could almost reach up and touch the feedlines. I accidently did touch one of the 50 KW lines and once burned was twice shy!

The cleared trees were cork oaks and supplied fuel for our fireplaces for years.

Best regards, Richard Harrison, KB5WZI

Thanks, Doc.

I have had a couple responses similar to yours, mentioning that a wire dipole is meant to be out in the open, so the results might not be as expected. At least if I try it and it doesn't work well, I can take it down and try it somewhere else. Worst case, it would be a relatively inexpensive education.

It might be a while, but I will post the results.

776. RFI problem on 75Mtrs in 95 Dodge Caravan

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-14 04:37:56 UTC
From: Dennis Dworak <ddworak@itol.com>
Message-ID: <3DAA4A24.49D795CB@itol.com>
Source record: 133164

Help
I have a 95 Dodge Caravan and had an outbackerhp on a
magnetic mount on the roof. I run a Yaesu FT-900 feeding
an Ameritron ALS-500mobile amp. With the outbacker on
the roof I could run full power on all bands with no problem.

Recently I sold the outbacker high power and installed a
Predator (N9JMX) screwdriver antenna at the left rear corner
of my van. I can run full power (500 watts) on 40 mtrs and on
20 mtrs etc with no problem. But when I try to run high power
on 75 mtrs it kills my engine immediately. I have very good
short grounds to my equipment. I used the power control on
the ft-900 and can run the power up to 200 watts with no
problem. As soon as I get over 200 watts it kills the engine.
I removed my center mounted glove box so that the vehicle
computers and wiring are exposed and tried gound cables on
the computers and even tried aluminum foil shielding of the
computers and wiring to them but it didn't help. Also when I
transmit at high power there is no dash lights flickering or
any other strange things happening. It just kills the engine
dead like you turned off the switch. I don't know
where to go next. Any suggestions of web sites or help places
anyone can give me would be appreciated. This is a very
frustating problem. 73

I would say because Windows 98 isnt supported anymore, so fixes for various things wont be displayed. All Windows OS's for the most part have issues, so after a few years they say forget it and move on. Xp is a little bit more resourse intensive. But XP does handle Multi monitor video cards a LOT better than win98. I run 4 Linux boxes and a Windows 2000 Server box or to, so take what I say for what you will!

Chuck,
Yes, it's done fairly often, they even make a
bracket to do it with. How well does it work?
That just depends on what you expect. It will
have a fairly narrow usable bandwidth on the lower
bands, widening as frequency goes up. The same
as a mobile antenna. So, all things considered,
they work pretty good...

Are you sure it's RFI?

There couldn't be anything strange happening with current draw at that
frequency due to antenna and amp combination could there?

I used to run a big inverter off a boat engine and certain inductive loads
used to kill the engine simply by the massive sudden current draw creating
too much resistance in the alternator!

Believe what? The T2FD is a better antenna than the Maxcom/Match-all at most
frequencies. But neither is near as good as half-wave dipole on its design
frequency!

> At the moment I feel that if it has a resistor in
>it...it has LOSS. And that translates to lower efficiency...in my mind
>anyway.

In reality, too. Why do you think the "Match All" is rated for 80 degree
temperature rise?
>
>Prove me wrong. Where is the antenna range testing?

Good simulation will tell the same things. W4RNL's data shows the T2FD to be
less efficient than a simple dipole - often much less efficient.

But here's the rub: It's a decibel thing.

Suppose a particular station using a half-wave dipole (efficiency almost 100%)
is heard S9+20 dB over a particular path. Now suppose the efficient half-wave
dipole is replaced by a resistive loaded antenna of the same pattern with an
efficiency of just 1% (that means 99% of the transmitter power is turned into
heat rather than being radiated). Suppose nothing else changes. The S9+20
signal will drop to S9.

Even a blind squirrel finds some nuts. And a broken clock is right once or
twice a day.

Uncle Peter wrote:
"Even if you use coax for the indoor portion of the run, noise can couple to the outside of the braid and travel back to the antenna wire in the common mode fashion."

Yes. More simply, unless the coax shield is grounded, it`s as if the shield wasn`t there.

If grounded, the shield may do bad things to the signal due to mismatch between the antenna and coax.

Banana plugs are OK. The UHF coax receptacle was designed to accept a banana plug. But for the coax to be effective, a shield connection is needed too.

But, strange as it seems, in some uses at some frequencies, it can
radiate more signal that a halfwave dipole! IE at the higher HF
frequencies it becomes a gain antenna for some directions, and can
actually beat a dipole for some uses in some orientations.

Yep, Jim, and that's a far worse case that most of the usual operation
experienced by users of a T2FD. I had occasion to use one quite a lot at
work, in a non-amateur setting, and you'd be surprised how well they
work when you aren't involved in "thinking about the technical aspects"
of them. I know I was sure surprised. I met a statewide emergency
communications HF net on a 8mhz frequency, where every station ran 100
watts to a B&W T2FD. If I hadn't known what they were using I'd have
never guessed from the way it all worked. Signals from all over the
state were always good and even the most distant stations up to 300
miles away were always good quality. Of course it was a dedicated
frequency without QRM. But the things worked MUCH better than I had
expected.
That's why the B&W's were used so extensively in US Government
operations. Users had to do no more than hang the darn thing, connect
the coax feedline, and go on the air, almost always successfully. Proves
the point that antennas of the best efficiency is not always what you
need. Sometimes it's something simple to use that works well enough.
These things can be used by people with *no* technical knowledge, a
radio version of 'plug and pray'. <g>

If the thing happens to radiate half the RF you feed it, chances are
you'll never miss the other half unless you're watching an S-meter and
happen to be a picky ham.<g>

My experience with them was the reason I bought one when it showed up
at a really good price at a hamfest. So far I've not used it, but have

it for whenever I might want to, and I can experiment with changes to its configuration as I want. And the matching transformer and terminating resistor are worth what I have in it.

> Even a blind squirrel finds some nuts. And a broken clock is right once or
> twice a day.

That must be the East Coast version. Out here in the hinterlands it's "Even a blind sow occasionally finds an acorn".

I just ordered that radio last night, with the Diamond HV7A quad band
antenna. You can buy extra parts for it to use it on other HF bands.
You will always have 6/2/70cm, but you can replace the 10m element
with a number of other HF bands. I bought the Diamond K600M trunk lip
mount for it as well. I'm very excited about this new toy! :)

Hi Richard,

That, in effect through modeling with EZNEC, is exactly what I did,
and the standard of 196mV was never observed (except as a consequence
of building a large receive antenna) much less a way to wrangle the
numbers into a 196mV/M relationship:
>> for a 1M tall user antenna, the load sees 317ï¿½V
>0.317mV/M not 196 mV/M (a -56dB discrepancy from the beginning)
>> for a 20 foot (6M) tall user antenna, the load sees 8.98mV
>1.5mV/M not 196 mV/M NOR 6 X 196 mV/M
>> for a 10M tall user antenna, the load sees 23.6mV
>2.36mV/M not 196 mV/M NOR 10 X 196 mV/M
>> for a 20M tall user antenna, the load sees 88.4mV
>4.42mV/M not 196 mV/M NOR 20 X 196 mV/M
>and so on up the line.

This leads me to believe that the "Fantastic, Magical RF Voltmeter"
fitted with probes with a 1M spread actually measures 317ï¿½V to full
scale, but the scale is printed with 196mV/M instead. I suppose if
you bought the cheaper, less sensitive MFJ version of the "Fantastic,
Magical RF Voltmeter," that it would require the longer 10M leads to
measure 23.6mV to be represented as 200mV/M (close enough).

Oh dear! I did something nearly as bad.
At a 'special event' station, I distinctly remember using a coax-fed 20m
dipole on 40m (tuner at the TX end). It seemed to work well enough to
get several (winter) daylight contacts up to 100 miles. Where did I go
wrong?

The horizontal configuration using two hamsticks works reasonably well
for 20m-10m. Not well for 30m. Less well for 40m. Pretty sad performance
on 75m. If you are running 100w, two 75m dipoled hamsticks are pretty
good for QRP operation. OTOH, some of us believe life is too short for
QRP. :-)

OTOH, any dipole that is 1/2WL on the lowest frequency of operation can
be tuned to resonance at the transmitter end by varying the length of
the ladder-line feedline. I show how to do it on my web page.

Heh, heh, I used to work for Schlumberger in the oil fields. To obtain complete coverage of all of South Texas, we had to run relatively high power on our mobile labs. I would wait for some roughneck to wander close to the mobile antenna wearing a hard hat and then hit the transmit button. Given the size of the South Texas mosquitoes, most of them thought they had been bitten. :-)

That's understandable since the outbacker is about 8dB down from
a good bugcatcher.

> Recently I sold the outbacker high power and installed a

If your outbacker had been more efficient, it would probably
have done the same thing. With a screwdriver, you radiate as
much power without the amp as you did with the amp and outbacker.
(If you don't realize it, this is actually good news.)

795. Yaesu ATAS-100 Antenna QUESTIONS

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-14 21:23:59 UTC
From: Mike Green KQ6MU <radiotek@pacbell.net>
Message-ID: <hedmqucoj4e4tal9u2sdjq1tt6nqr2il4e@4ax.com>
Source record: 133033

Greetings,

I have some questions regarding the Yaesu ATAS-100 Mobile Antenna.

I just purchased the Yaesu FT-100D to use in my car (Ford Escort). I used the FT-100 when riding with a friend, and it seemed to perform well and the ease of operation with the ATAS-100 was exciting and simple.

Questions:

1) Antenna Mount Choices: Now, I really do not want to drill holes or anything that would damage the vehicle. I am looking at the Lakeview Quad Magnet Mount or Super Quad Magnet Mount on the Mag-mount side, the Trunk Lip or License Plate Mount (Lakeview) for more security knowing the antenna won't fly away.

I am aiming towards the Mag-Mounts, at this time. Will the Quad Magnet mounts have enough strength to hold this antenna to the vehicle? I would like to use it on the center of the roof, or, if necessary, on the trunk lid. Will the wind load (80-90 MPH max on the road) cause the mount to detach, or does it have sufficient holding strength?

2) PERFORMANCE: I have read tons of review on eHam, and would like to receive a few more. The reason(s) why I am choosing the ATAS-100, is due to ease of operation and decent efficiency. I don't want an antenna that will be cumbersome or "offensive." I think other Screw Driver Antennas (such as Don Johnson's Screw Driver) would be a little too large for this car to handle without a lot of construction work with the mount. Also, I don't want to stop and replace a jumper or resonator to change bands. Pros and Cons would be great!

That about does it, and I thank you for taking your time to assist me on my HF Mobile Setup. I can't operate from my home, so this is the next best thing. See ya'll on the Air & 73!

Please Email response to: radiotek@pacbell.net

Hi, Guys...

I'm finally moving to a retirement location where I can put up a beam!
But... it's a beautiful flat valley between two ranges of 400-500' hills.
North and South are pretty clear. To the east, the hills crest probably
3/4 to 1 mile away. West, mmm maybe 1/2-3/4. Haven't been able to measure
but I suspect takeoff angle to clear the hills will.be 30 degrees.

I'd like to have something fairly large, hopefully with some gain & F/B on
40m. Probably Force 12. Am I wrong to think I might be better off with
the antenna on a fairly short (35-40 ft.) tower for a higher takeoff angle?
Or do you think a beam's performance will be too compromised with unwanted
reflections to show useful gain and directivity. (Sorry, I've never been
able to get any meaningful results from a modeling program --guess I'm too
old to learn-- so thought I would ask here.)

Comments? Suggestion?

Thanks... Ed, W5EJ

There used to be an animal called "72 ohm twin lead". I remember buying 100 feet of it from Harrison Radio on Radio Row in NYC. It was about a tenth the cost of even the cheapest RG-58. I made a dipole of some #18 stranded copper they sold at the corner hardware store and connected the thing to the terminals at the back of my WRL Globe Chief 90a. I worked all over the East Coast with that setup and some on screen modulated am. I wonder if they still sell that stuff? Point is it looked exactly like lamp cord!

Hi Ed,

Tsk, tsk - 30 degrees indeed!

Let's take the worst case: for a run of 1/2 mile the land rises 500
feet. This is a classic rise/run that resolves through the inverse
tangent to reveal
tan theta = 500/2640
theta = arctan (0.1894)
theta = 10.7 degrees

A short tower has never been an optimal selection for any beam that I
am aware of (unless it's a fractal perhaps). Anyway, your absolute
worst case still provides plenty of DX angles (and knife edge
diffraction will actually lower that 11ï¿½ somewhat).

By the way, your description of a flat valley and my worst case
scenario are competing for a reality check. With an 19% slope, that
is one wicked climb and would be immediately noticeable - and never
described as a "flat."

Hi, everyone.

I am getting "previously enjoyed" 6-el KLM monobanders for 10 and 15 meters, but the seller does not have manuals anymore. Is there anyone out there who can scan or photocopy them for me (at least the diagram). I'll pay any reasonable fee. Search on Google turned out zip.

Thanks and 73,

Zoran WA7AA

microvolts to full scale, but the scale is printed with 196 mVm
instead."

Possibly so, and fair enough. So long as the indication squares with the actual field it`s OK.

I`m puzzled as to wahat troubles Richard Clark. I doubt it`s the field produced at one mile by one kilowatt. Many different numbers are found for this in the literature, but they are explained by the different circumstances such as transmitting antenna, the propagation path, etc.

For example, a 1/2-wave dipole in free space is said to produce about 138 mV/m at one mile, not 196 mVm that the 1/4-wave over an excellent reflector produces. This squares with twice the power from the 1/4-wave antenna because half the available power can`t flee through that excellent reflector under the antenna and its transmission path. It must be transmitted in the upper hemisphere.

I doubt that Richard Clark challenges the 6 db decline in field strength power every time the distance doubles from the transmitter in the far field, due to spatial spread. That`s just geometry.

I doubt that Richard Clark challenges antenna reciprocity. A current in a wire produces a certain field. A certain field conversely produces a certain current in a wire. The actual mechanism can be tedious because there are many degrees of freedom. The best reference I have is from King, Mimno, and Wing. The most readable reference I have is Terman`s section on "Behavior of Antennas When Receiving Radio Signals".

The formulas are too involved for me to reproduce here.

Having measured fields countless times I`m a believer.

Best regards, Richard Harrison, KB5WZI

807. Trunk mount question

Newsgroup: rec.radio.amateur.antenna

First, I would not assume that the trunk lid is well grounded - it sits on a rubber gasket and the only path to ground it through the hinges and the latch. Nice, flat, braid to the main body panels would be much better.

Seems that way when all signals are attenuated by the same factor
which doesn't affect the intended communication.

If you have a coax-fed antenna with the coax coming into the house, a good way to check the noise level that you would be picking up if you were using a single wire feedline is to unscrew the barrel of the PL259 and slightly pull the PL259 from its jack so that the center pin still makes contact but the shield (barrel) does not. That takes the shield braid out of the picture. If you have any noise generated within the house (who doesn't?) it'll sure show up. TV birdies are everywhere there is humanity, it seems.

Hi Richard,

Well, yes, but no further than described. Let's say I was looking for
an absolute result, rather than a relative one.

Also, this bears on a comment you offered:
>A 20-foot vertical antenna is about 6 meters and capable of 6x10 mV/m at
>20 miles from the 1 KW station.. 60 mV/m
Which suggests antenna gain is a linear function of length (my model
suggests for short antennas it is a power progression, not a linear
progression).

My model represents that 196mV/M radically overstates what is
available to a 1M antenna (merely 317ï¿½V/M in a modeled application)
and that an antenna 6 times larger does not have 6 times that amount
(rather it has 8.98mV or 28 times larger!).

This leads me to observe that technical usage of V/M is ill-suited to
translating those terms to actual potentials seen by a receiver.

I'm delighted with my MQ-2. I imagine there is little to choose
between the two in terms of performance. The MQ-2 got the nod
over the MA5B when I was deciding because it includes 6 meters
and is a bit smaller. 6 meters tunes fine using the internal
tuner in the IC 746.

I would recommend against using a mag mount for the ATAS-100 for the simple reason that this antenna MUST be well grounded. Failure to do so may result in burning out the antenna. I know this from sad experience. When using an ATAS-100 antenna, ground the antenna AND the radio WELL!

817. Gamma rod construction question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-15 04:39:12 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3DAB9BFA.EC8A807E@bellatlantic.net>
Source record: 133057

I'm building a 4 element 6 meter beam. I'll be
running 100 watts.

The gamma rod is fixed. One end is screwed to the center
of the S0-239 with a 6-32 brass screw & nuts. The screw
was ground down to fit into the center pin on the S0-239,
and soldered in place. The center conductor plus insulation
of RG8 slides in this rod (3/8" tube) and the end is attached
to the driven element with a sliding clip.

The gamma rod is 1 1/2" below the driven element.
The question:
Is it ok to use PVC plumbing pipe as the stand off between
the gamma rod & driven element? The rod will pass thru a
hole in the PVC pipe, and the driven element will pass through
another hole. I've tried it - mechanically it is really sturdy,
but I don't know if it will stand up to sunlight/whatever.

818. Comet SBB-7

I need help tuning a Comet SBB-7 antenna. It is a 146-450 antenna with two loading coils. I can tune the 144-148 mhz from about 1.0 to about 1.4. But the 440 region gives me trouble. I can tune the antenna from 440-447 to about 1.5, but from 448-450, the SWR spikes. Literally goes off the meter. Any help?

If you have the SO239 end mechanically secured- and it sounds as though you do- then the other end needs to be a conductive connection from the gamma rod to the driven element- I don't see why you need the PVC standoff.

Scott
You said "the twin lead needs to come off the other elements
at 90 degrees and should be straight out". My question is can that
be straight out 90 deg horizontal making the G5RV like a big "T"
in the air without the twinlead being vertical at all?
I'm trying to figure out what kind of antenna to run as soon as
I upgrade, and needless to say I want to do it the traditional ham
way, in other words "As Cheap As Possible" ;^)

I've had my ATAS100 mounted to the roof of my 4Runner for a couple of years now using a tri-mag mount. It has performed flawlessly and has survived speeds in the 80mph + range. At least two other local hams have the same or similar setup and I've not heard of their antennas achieving low earth orbit yet either.

StarGazer wrote:
>
> How far off resonance do you have to be before using coax
> will significantly affect the antenna system performance.
> I'm still using a tuner to get a 1:1 SWR.

Operating a feedline at VSWR greater than 1 increases the feedline losses. The higher the matched line loss and the higher the VSWR, the greater the loss. Higher VSWR may be more tolerable on a lower loss cable, or higher cable loss may be more tolerable with low VSWR.

>
> I have about 4:1 on the bottom of 80 m and tune it out with
> the tuner.

You haven't told us the cable loss, so the answer depends on some unknowns.

For example, if you were using 100ft of RG58CU at 3.5MHz on an antenna, and you measured VSWR=4 at the transmitter end of the feedline, matched line loss would be around 0.8dB and the additional loss due to the VSWR would be around 1.2dB, giving a total cable loss of around 2dB. A bit shabby, but not real bad - 62% of the power from the tuner is reaching the antenna.

But, if you were using 30ft of RG213 at 3.5MHz on a different antenna, and you measured VSWR=4 at the transmitter end of the feedline, matched line loss would be around 0.1dB and the additional loss due to the VSWR would be around 0.1dB, giving a total cable loss of around 0.2dB. Pretty reasonable - 95% of the power from the tuner is reaching the antenna.

So you see, it depends on the matched line loss and the VSWR.

Beware of the unstated qualifications that make broad statements valid.

Owen

PS: don't overlook that the antenna in the first scenario has a VSWR of about 6 at the antenna terminals, and if you replaced the cable with 30 ft of RG213 (shorter, better cable, lower loss) you should see a VSWR around 5.6 at the transmitter end of the feedline and the total cable loss would be around 0.3dB - 93% of the power from the tuner is reaching the antenna.

(The analysis ignores the losses in the antenna tuner, which should be less than 0.3dB in each scenario.)

(Someone will probably check the numbers - did I get the maths right?)

Actually, I would say that short vertical monopoles, even
when placed over a perfect ground, are ill-suited to
translate electric field strength into terminal voltage.

First of all, the current distribution on a short monopole
(h < 0.1 wavelength) is approximately triangular in shape
rather than uniform. This results in an open-circuit
voltage at its base with respect to ground of *one-half*
the value of the incident electric field times the
monpole height. In other words, its effective height
is 1/2 its physical height.

Secondly, the induced voltage is in series with the
self-impedance of the monopole. For a 1-meter monopole
at 1 MHz, that's a few milliohms radiation resistance
in series with approximately 9500 ohms of capacitive
reactance. For the specified termination resistance,
1000 ohms, most of the induced voltage will be dropped
across that capacitive reactance. A more effective
termination would be that used with the so-called
'active antennas' - a resistor in the 10's of megohms
to ground (and closely connected to the gate of a
small MOSFET source-follower buffer).

The usual practice, as Richard Harrison has pointed
out, is to use a small loop antenna to measure the
magnetic field strength and translate that into
electric field strength in V/M by assuming a TEM
wave in free space (ie: make the measurement outdoors).
The small loop has the great advantage that its
self-impedance is a small resistance in series
with an equally small inductive reactance that can
easily drive more conventional receiver inputs.

As far as electric field strength being specified
in volts/meter - sorry guys, it's the Law (Gauss'
Law, that is).

Richard Clark, KB7QHC wrote:
"Let`s say I was looking for an absolute result, rather than a relative one."

Volts per meter means volts per meter when the length is short compared with wavelength.

Power doesn`t increase with the square of the voltage because the matched load resistance is linearly rising with the length of the short antenna. The load equals the radiation resistance. We tune for a conjugate match.

Certainly true. Efficiency of mobile antennas is a case in point. (They are reciprocal devices.) The advantages are small air space and operation in all horizontal directions without specific directional positioning. Despite disadvantages, short whips are used for groundwaves because there is no horizontally polarized groundwave and because omnidirectionality is a virtue in many situations.

"My model represents that 196 mV/m radically overstates what is
available to a 1-meter antenna (merely 0.317 mV/m in a modeled
application) and that an antenna 6 times longer does not have that
amount (rather it has 8.98 mv or 28 times larger!).

Aha! 196 mV/m from 1 KW at 1 mile from a 1/4-wave vertical antenna at 1 MHz over a highly conductive path is reported by many authors. They may have copied each other`s work, still they can`t all be that far wrong.

I have no experimental measurements at hand, but that size discrepancy could be crudely checked with 2 lengths of wire and an "S" meter.

I installed a "Long Ranger" 100-inch maximum, which collapsed into less than 1 meter by telescopic action, antenna on my 1940 Ford. I was a teen-ager then. I wanted such an antenna because I listened to distant AM stations at night. My recollection is, AVC not withstanding, that the volume increase was more consistent with a linear increase of signal strength than an exponential increase when lengthening the antenna. My crummy radio may account for that. You sometimes had to kick it to start the vibrator.

Best regards, Richard Harrison, KB5WZI

Do you have electric power to the barn? Or an outside light on a pole nearby? If so it's coming right back into the house via the pole transformer secondary.
When I had my HF antennas close to the house I *always* had troublesome RFI. After moving them all to a tower less than 100 feet away from the building, I haven't seen any sign of it since, even though my 160 meter dipole, paralleled onto 80 and 40 meter dipoles, comes within several feet of an outside overhead triplex that feeds my workshop. It is at right angles to that AC feed, though.
That makes a difference. If the antenna is more parallel to the AC wiring it induces a lot more RF onto it.
I'm convinced, although as always, individual installations will differ.

But the simple, broad answer still stands - on a single band, with the
possible exception of the 10 meter band, replacing his coax with
ladderline and a tuner won't perceptibly improve his situation.

Source record: 132932

Hello,

maybe this is an old question, but I haven't found an answer yet.

Why is bare copper preferred for a dipole antenna on HF ?
Why do textbooks say so ?

My dipole is made from a single wire, black insulated number 12 AWG
multi strand "house wire": seems to work OK.
It would need more height, but thats another story...

Would it work "better" with bare wire ?
I'm not sure but it seems to affect the velocity factor ?

Thanks for any help

Should last for quite a while. There is little stress on the plastic.
I did much the same thing on mine, except that I used flat pieces of
plastic. After building it, I decided it could be welded in place, but
I haven't done it yet.

Correction!

I should have consulted Terman. My memory is faulty. On page 655 of the 1937 edition of "Radio Engineering":

"Under these conditions (loss is insignificant) the rate at which energy is abstracted from the wave is (volts per meter x effective antenna height in meters) squared, divided by twice the radiation resistance, and since half of this is reradiated, the maximum possible amount of power that can be delivered to a load resistance is half the power above."

That looks to me like the dimensions of 1/2 E squared over R, because half the energy is reradiated.

On page 713, Terman writes:
"The energy that an antenna is able to deliver to a radio receiver depends upon the physical size of the antenna, the frequency, and the antenna efficiency as defined for transmission. If the efficiency is high, i.e., if the antenna resistance is largely radiation resistance, the energy that can be abstracted from a passing radio wave tends to be independent of size until the antenna dimensions approach a half wave length. This is because the equivalent lumped voltage induced in such an antenna is approximately proportional to size (my contention) while the radiation resistance is proportional to the square of the size."

My mistake! Recalling incorrectly the shape of radiation resistance versus antenna length (height) curves. I wrongly said radiation resistance was a linear function for electrically small antennas.

I apologize.

Best regards, Richard Harrison, KB5WZI

> mirage.

I won't go as far as horsehocky, but I'd be very leary of the improved
bandwidth. Lets look at it from a wire dia angle. On 160m, to show a
decent decrease in Q, I would think you would need a huge dia
radiator. And I'm just guessing, but I would think offhand, that the
shorter the antenna, the more you might notice the improved bandwidth.
IE: many mobile op's try to use fat lower masts. If you look at it
from a "bazooka" standpoint, it's already been proven that the
increase in bandwidth is due to loss in the coax. Now, the loss in
coax is pretty low on 160m, so this "shouldn't" be a large factor.
Would depend on the type and quality of coax.
I have to wonder if the same ground radial system is being used on
both antennas. This could have a large effect if the first antenna had
many radials, but the 2nd "bazooka" wire had fewer radials. Myself,
I'd be scratching my head wondering where any extra losses would be.
If both antennas are the same height, and both use the same radial
set, etc, and antenna B shows a much wider bandwidth, I'd be thinking
excess loss is the reason. I've had a number of 160m antennas, L's,
T's, dipoles, etc, etc, and I don't remember one of them that would
cover the whole band without help from a tuner. Now, if f/s and on air
tests seem to indicate that the antenna is working as well as the
first one, well, heck, I'd probably use it, loss or not. But I'd still
be scratching my head....I'm wondering which antenna actually radiates
the best. As a general rule, improving a vertical will raise the Q,
not lower it. I don't doubt there are exceptions though in some cases.

Stephan,

I don't think there is any measurable difference between bare and insulated,
or solid and stranded wire at HF. Solid wire is more likely to break from
flexing. Put your effort into getting either one as high as possible.

Hi Dick,

Such loading doesn't work as well at the tip as it does beneath a
capacity hat. However, since this suggestion relates to the hat,
perhaps each spoke of this wound hat lead should terminate in its own
hat at THAT end.

Electrically it will not make any differance below 30 mhz or so. Maybe at 10 meters it could make the antenna a few inches shorter, but most of the time you will be cutting it for minimum SWR anyway.

Dale,

Thanks - I guess I did not make it clear. One end of the
gamma rod (3/8" tube) is connected to the center pin of the
S0-239. The rod (tube) is thus mechanically secure at that end.
It forms part of a trombone capacitor. The other end can flop
around unless I use an insulating material to secure it. The
electrical connection is through the trombone capacitor to the
driven element. The capacitor is made by sliding a length of
center conductor (plus insulation) of RG 8U into the gamma
rod (tube). You just strip the insulation and the shield. The
"rod" part of the gamma is that insulated wire, and it is
electrically (and mechanically) connected to the driven
element.

Mark,

Thanks. I've used plexiglass before, but I've heard it
becomes brittle when exposed to the elements over time.
I don't know if that's true - but I decided to alter
my approach based on that. I'll go with the PVC pipe.

My modeling suggests that V/M is meaningless in the face of a real 1 meter wire doublet feeding a real load. That is, with 1 meter leads (which conforms to the constraint of being short) I do not get 196mV for that same meter of wire (for ANY size load). In fact I get nothing near 196mV - 317ï¿½V (a -56dB discrepancy from the offered standard field value). This suggests that knowing V/M and trying to translate that into a known voltage applied to a receiver is utterly useless. That is, unless you have a modeler, and even then it doesn't give a damn about V/M either.

>
>Best regards, Richard Harrison, KB5WZI

Hi Richard,

Am I to infer that field strength meters are conjugately matched then? If I were to load the 1 meter leads to their consequent radiation resistance, I am fully sure that the already dismal -56dB correction factor for voltages would sink even further. Having never observed any field strength meter with load tuning provisions, it seems unlikely that is an option (or that it is even considered necessary to perform this conjugation).

If this appears to be a conundrum, it would further understanding if someone could offer an explanation as just how to get 196mV out of 1 meter of wire (or even half that 196mV, or a third, or a tenth, or a hundredth).

The application of V/M in a thread wanting to know how to build an AM antenna seems to be as useless as tits on a boar hog.

Stephan,
While there is some slight difference between the 'VF'
of bare and insulated wire, it's very small. The difference
in length it would make is compensated for, or 'taken care'
of, when the antenna is 'trimmed' for resonance. I would
think that the primary difference between solid and stranded
wire is mechanical, which would stand up to movement of the
antenna 'better'. Again, the difference will probably be
very little. Maybe a difference in surface area per size of
wire? That's really 'pushing it' though!
For all practical purposes, there is no difference between
solid or stranded, insulated or not, especially at HF...

You're gonna find PVC will turn to dust long before plexiglass.
I once built a 'long-boom' UHF Yagi for TV ch's 73-77 using
PVC pipe for the boom and braces. Worked quit well for a few
years. Then a (small) windstorm brought it down. The stuff
would crumble, easily, with your fingers.
Of course, here at 7,700' (2,350M) and year-round brilliant
blue skies, the process would be accelerated for me.
Again, here at 7,700', I've _never_ seen any problems with
out-of-doors use with plexiglass.

I can fully imagine that they are exactly right. But this says nothing of what was actually measured; rather it merely suggests that correlations were maintained.

And this goes to the heart of the matter. The 196mV/M was for a receiving antenna of one quarter wavelength in size? I have observed no comment to this matter, and yet a 1 meter length antenna obviously does not present 196mV to ANY load for any of its full 1 meter length. This real 1 meter doesn't even see 1% of 196mV for that same 1 meter specified.

>
>Best regards, Richard Harrison, KB5WZI

Hi Richard,

You make my point above by reciting how a longer AM antenna outperforms a shorter one. Your logic suggests otherwise, but the testimony of your perception argues successfully against your logic. Perceptions (all human forms of contact with the real world) are power progressions (that is, our sensing of the real world is log based, not linear). That your testimony consists of the sensation of hearing, a

very strong non-linear system, and concomitant with a linear increase with the antenna length is prima facia evidence of a power progression and conforms to the data of my model. You make the aside of "AVC not withstanding" which, again, more compelling argues for a power, not a linear, progression of sensitivity.

When you had a choice between an antenna 100 inches long, compared to its collapsed 1M form, the longer was clearly stronger. However, given the nature of senses (hearing again), the difference by your computation of V/M would suggest you could hear the difference of your linear-law gain of 2.5-fold and dismiss my suggestion (supported by my model's results) that it was actually a power-law gain closer to 7-fold for the same extension of wire. Again, the testimony of your senses favors a more vigorous boost found in the power progression not a weak linear one.

To apply this V/M to receive antenna characterization robs real gain hand over fist. This leads me to believe that the V/M characteristic is not to be applied to wire translations of field characteristics to front end potentials. There appears to be a every chance of mis-interpretation (like the linear gain of potential with the linear gain of length), and almost no chance of actual, useful or accurate translation (as evidenced by the glaring -56dB disconnect between the specified 196mV/M offered and the real 317ï¿½V/M applied to the load).

Hi Jim,

Your statement above is a form of infinite regress. That is, you have taken a physical form, translated it into an electrical equivalent, taken that electrical equivalent to cast it back into a smaller physical form. The unbounded regressive repetition of this argument devolves into a senseless conclusion that no antenna is useful because it is always shorter than it appears to be.

Such regressions then have to support the inevitable question driven by contrary real world evidence: when does this antenna become large enough (no longer short) for this logic to become invalid? You suggest that is 0.1 wavelength. Is that to suggest that a 0.10001 wavelength antenna has a constant current distribution out to the end? No, that isn't even true for 0.25 (which exhibits the identical open-circuit at the same end, long or short).

So, as a long or short antenna, the same problem exists at the same end, and yet the logic of the infinite regress is suspended for the longer one (despite the same logical constraints).

Infinite regressions often give the appearance of magic as a major component to the "logic" of the statement.

PVC plumbing pipe does not contain Ultraviolet Inhibitors in the
plastic. It will turn brittle in exposed sunlight after a few years.
However, the solution to that is quite simple, paint it first. A couple
of coats of a good outdoors latex paint will shield the pipe and
increase the live 5X.

A bare wire is always less lossy than an identical wire with insulation since the insulation has dielectric losses. Those textbooks can back up their claims with 0.1 dB loss calculations. :-) I'm a purist but I used insulated wire in AZ to reduce the wind-induced static. Not a problem in Phoenix or East Texas, but the Damned Yankee Hams tell me that there is such a thing as snow-induced static which can be reduced by using insulated wire.

PVC certainly becomes brittle and shatters over time
when exposed to UV. If I were you, I would use LEXAN(R)
which, if I remember right, is a polycarbonate and is
used for airplane windshields.

For the same copper size, won't the insulated wire have greater mass and
more importantly in most applications, higher wind resistance?

Peter Ward wrote:
"---I want a stand alone vertical AM antenna so it need not be adjusted for directions."

We strayed into the minutia when I should have gone straight away to Terman for a definitive answer. It`s found on page 714 of the 1937 edition of "Radio Engineering":
"When it is desired to avoid marked directional effects in the reception of signals of broadcast and lower frequencies, a single wire with one end elevated and the other grounded through the receiver (input) is ordinarily used. The height rather than the length of such an antenna determines the induced voltage since waves of broadcast and lower frequencies are vertically polarized in the vivimity of the earth. A height of only a few feet is sufficient if great care is taken to eliminate all loss resistance and to match the receiver input perfectly with the antenna (as might be attempted in a car radio), but it is usually simpler to make the height at least 15 to 20 feet so that the penalty of not realizing ideal conditions is less.

Consider the only slightly enhanced following story. The temperature in Phoenix is 122 degrees F. You are out in your yard trying to trim your multiple dipoles to resonance on all HF bands. You have been at it for three hours. Doesn't it make sense to settle on a single dipole fed with near lossless transmission line and move the matching problem into the hamshack which is air-conditioned at 68 degrees? :-)

Hi all

I hope someone out there may be able to help

I remember a while back a radio ham who lived next to me gave me a calculation you could use to work out what length the ant should be at a set freq. such as 16" for 169mhz

He's long and gone now sadly but I cant for the life of me remember what the calculation was anyone out there in cyber land help us out.

Thanks guys

Paul

> Why do textbooks say so ?
==========

(1) Because insulating materials make the antenna heavier for the same amount of copper. This increases the cost of supporting it.

(2) Because the radio textbooks you read are plagiarised from 'comic' papers.

Paul Henry wrote:
"---what length the antenna should be at a set frequency such as 16 inches for 169 MHz?"

Paul`s example is close to a 1/4-wave. Meters of wavelength in free-space is 300 divided by the frequency in MHz (close enough).

For Paul`s 169 MHz, the wavelength in free-space 1.775m using 300 / MHz. For a 1/4-wave, divide by 4. My calculator gives 0.444 meters. There are 3.28 feet in a meter so, the length is 1.46 feet or 17.47 inches.

The wire slows the traveling wave depending on the length to dianeter ratio of the wire. Sometimes this is estimated as shortening the usual wire to 95% of the free-space length, or in Paul`s example, 16.6 inches. The actual range, depending on the fatness of the wire usually varies between 92% and 98% of the free-space wavelength. 95% is thus a compromise value.

Sometimes the length of a 1/2-wave dipole in feet is said to be 468 divided by the MHz. This conversion includes the 5% reduction in length for "end effect" or a fat wire or whatever you want to call it. If you want the length of a 1/4-wave antenna, just divide the result of the 1/2-wave calculation by 2. Or before calculating the antenna length, use a numerator of 234 and divide it by the frequency in MHz.

Best regards, Richard Harrison, KB5WZI

877. Re: Why use bare wire ?

Newsgroup: rec.radio.amateur.antenna

I always use solid enamelled copper wire because its almost impossible to obtain the solid bare stuff.

And it's very difficult to wind your own close-wound tuning coils with bare wire.

To obtain bare solid wire it is necessary to persuade an enamelled copper wire manufacturer to sell you some before he enamells it.

He will probably charge you extra for the inconvenience caused and he won't be interested in lengths less than several miles. Only radio clubs will be interested.

The BNC has enough "give" where lateral antenna movement
allows the pin to spread the female center receptacle in some
instances. Do a visual inspection of the BNC antenna fitting
on the talkie, and see if it looks elongated. You might have
to compress the female jack, or replace the BNF connector.

If not, try some DeOXIT cleaner to remove the oxidation--be careful
that the cleaner doesn't react with the plastic case material!

There is no need to run dipoles in a straight line, Z-shaped dipoles
have been known to work quite well. Keep it away from metallic objects
and it won't hurt to use insulated wire. As far as length is concerned
there will no ill effects if you simply bend the ends down verticlly
for a couple feet to reduce the installation length four feet or so
while still achieving the proper resonant length. Much simpler than
getting involved with complexities like capacity hats particulary on
the higher HF bands like 20. Cut the antenna two feet longer than the
calculation indicates for your center frequency and nip off short
(3")equal lengths of wire from each end until you obtain the lowest
SWR.

OK, I've read all the replies thus far. Some say "there's a difference, but you probably won't notice it",
others say "There's no difference"

My own personal feeling is that you have to look at what you're gaining and/or losing in each decision.

Insulated wire will probably build up lots less static in a windstorm or a snowstorm. Whatever method you choose
to get rid of the static will probably be lossy; maybe more lossy than the difference between insulated and bare
wire.

I think when one figures in practical considerations, the theoretical differences will become lots less
important. Then, you have to figure you can get insulated wire at Home Depot cheap. I dunno, if you want to
agonize over fractions of a dB, be my guest. I'd go with whatever I could get my hands on. The fact that it
isn't gonna build up thousands of volts of static during a snowstorm is only a tiebreaker.

Cecil,
How do you calculate the LOSS on a wire that is insulated such as the new Steppir antenna? Can you calculate it from the resulting shorter radiating length, ie continuous loading as with say bare steel without insulation?
One person informed me that the resulting radiator antenna shortage was indicative of a more efficient radiator but did not explain efficiency with respect to length, radiation or what ever but did mention that the insulator SURFACE was what counted! I assumed that with a good insulator he was saying that the glass fibre SURFACE acted as a reflecting radiator! He was an expert (technical consultant)so I was left thoroughly confused .

Not quite. To predict the output voltage of an electrically
small monopole, the effective height has to be known. For
the simple case of a single, unobstructed, 1-meter vertical
rod, that's one-half its physical length. If you want to
work that particular case in reverse, from effective height
back to physical height, multiply the effective height by
two.

> Infinite regressions often give the appearance of magic

That to me is a real surprise! Lexan when subject to certain cleaners,
petrolium e.t.c develops crases (small fissures on its surface) that
ruins it
for such an aplication. I was awarded a medalion encapsulated in Lexan
which my wife cleaned and immediatly destroyed the surface
transparency.
I have also seen a Lexan article shatter into small pieces when
dropped which shocked a lot of people. This was caused because the
Lexan was not thoroughly
dried prior to molding. When all proper precautions are taken it is
extremely resistant to impact.

Hello all. I'm not sure how off topic my question is, but, it's kinda'sorta' based on my antenna. I'm going to be deep in the mountains of Colorado for a week, starting this Friday night (18 Oct). We'll be over an hour from any cell phone coverage and VHF/UHF repeaters. The only emergency comms we'll have is my mobile radio that I finally got set-up last week. I'm using an IC-706 barefoot, with an SGC-230 coupler and SGC-303 antenna. My personal experiences are that the antenna does pretty well on 20M and up (given only 2 days of use)...I'm assuming it will do okay on 40M as well, if I need to...?

If we have an emergency and need to call for help, what frequencies are best to use? The concern I have is that my non-licensed, non-tech friends won't know how to find/use freqs the way I might, not that I'm all that good at HF work myself... I'll show my friends how to use the radio (and give them a list of freqs to use)...so they can transmit a "mayday" if I'm disabled in some way.

Also, I'm not sure where my truck will be if it's needed--it could be a couple of hundred feet down in a rock-faced canyon (that's where our camp site is) or it could be high on the top of a mountain-top plateau.

Any thoughts/suggestions? Do the HF bands have "call" freqs that we should aim for? To date, I've not learned of any or noticed any such freqs. Finally, is anyone interested in trying to set-up a nightly chat on any particular freq, say around 1900 MST? Many thanks...

> Reg, what's the name of your program that > calculates the length of the
> matching section for a non-resonant >dipole?
==========

I don't recall having a program which does this directly.

First find dipole feedpoint impedance Zin = R+jX. You can use programs DIPOLE3 or DIPCAGE1 for this. (Don't expect them both to give the same answer. <grin>)

Then insert Zin into program MATCHSEC (matching section).

==========
It is frequently impossible to design a matching section having practical values of Zo which fits neatly between the antenna and the end of the feedline. But by allowing the matching section to be moved a short distance from the antenna towards the transmitter an extra degree of freedom becomes available. A match can still be maintained by moving the matching section a whole number of half-waves along the feedline nearer to the transmitter.

For given feedline Zo and antenna Zin, Program MATCHSEC allows a wider choice of Zo for the matching section. It then calculates the length of matching section and the length of feedline between matching section and antenna.

As a sideline, for given Zo, the program also calculates the wire spacing of balanced lines and the diameter of the outer conductor of coaxial lines, both line types being air-spaced.

Try not to forget the sign of Xin in Rin + jXin.

The ARRL band plans don't list any specific SSB calling frequencies
for 10 meters and longer.

My guess would be that frequencies just above the bottom of the band's
General-class phone sub-band would probably be the best place to start
calling.

In an emergency, the first thing I'd do in a case like this, probably,
would be to jump there, tune up a bit until I found a QSO in
progress, wait until a loud-and-clear voice _stopped_ talking, and
then start an emergency call. If you can hear 'em there's a
reasonable chance you can work 'em.

40M may be be dicey at night due to QRM from commercial AM
broadcasts in Europe. In a legitimate emergency you could transmit
SSB phone in the bottom CW portion of the band... there's a reasonable
chance someone would hear you, as some CW operators listen in SSB part
of the time. I'd probably try 20M first, though.

A low-mounted dipole would tend to give you a high radiation angle...
and for local emergency comms over distances of a couple of hundred
miles this isn't a bad thing, as high-angle skywave reflection would
work in your favor.

>(sorry about the dead e-mail address ... I hate spam and this
>technique works!)

I'd advise against using any similar technique when calling CQ on HF
>>grin<<

Yes, and more weight also. But I still prefer insulated stranded
copper wire for wire antennas myself. I use both #12 and #14. I'm
starting to prefer the #14 because it is lighter and plenty strong
enough. The wire doesn't corrode, it doesn't break easy, and I can
pick the color to blend with the qth. If there is any difference
between the two, I've never worried about it. It's so small I've never
been able to notice it. Plus, standard house wire is cheap. About
$19-$20 for 500 ft of 14 gauge stranded last time I looked. Thats been
a while, so don't know the current price of copper lately...And you
get to pick from many designer colors. I like light grey and light
blue. I'm starting to think I like the grey the best. It stands out
less running through trees, etc. The blue tends to reflect a lot of
light, and stand out if the sun is at the right angle. :(

also remember that who ever you get on the radio will be a long ways away
and not know where in the world you are so i would suggest a portable GPS
and also arrange for a fellow ham or hams in your home area to monitor a
given freq to listen for emergncy call could be a good think for a club to
help out with
the chances of you finding someone in your area (100-200miles) that would
have any idea who to call for help let alone where you are to get help
think about it someone in your party has fallen down a cliff or is snake
bit and needs help ASAP do you really want to rely on HF to get help from
people in far away areas or even another country by the time they figure
out who you are where exactly you are and who to contact for help the
people who was injured would be dead
good luck

900. Gamma match verse Hairpin match verse T match

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-16 03:49:01 UTC
From: Scott <scott2rp789@netscape.net>
Message-ID: <3DACE1AD.A20E0DA7@netscape.net>
Source record: 132990

I've read through the ARRL Handbook (18th) pretty thoroughly. It discusses the gamma and hairpin match (and others), but it doesn't really say much about about the pros and cons of them. I know the gamma match was widely used in the past. I see the T match and hairpin match being used on newer HF beams and some VHF antennas. What are the advantages of the T match and Hairpin match over the good old gamma match?

Scott.

Fred Hambrecht wrote:
"divide the desired frequency into 2856 for the length of a 1/4 wave antenna in inches."

When 234 is multiplied by 12, the product is 2808 for the calculation of a 1/4-wave antenna in inches. Using 2856 will produce a dividend about 1.7% longer than using 2808. No big deal. For the 169 MHz antenna, the "wire" is likely a self-supporting rod. This will be on the fat side of L/d`s. Velocity will be on the slow side, so not so much length is needed to complete 90 degrees. My guess is that 2808 will come closer to 1/4 wave when divided by 169 MHz for the required number of inches. The dividend is 16.6 inches..

1.7% longer won`t hurt, and will ensure there`s enough to trim for exact resonance if that`s your pleasure.

Best regards, Richard Harrison, KB5WZI

Om 40, 7255 and 7258 are (or were) active, with the Midwest Amateur Radio Service known as MIDCARS occupying 7258, and WESTCARS on 7255. Last time I checked (been a few months) MIDCARS was active but I have no information on the status of WESTCARS on the west coast. Generally populated by retired geezers with nothing better to do <g> and are glad to assist anytime. Problem is coverage and activity tends to be spotty depending on who is interested and available at any given time. They would be good spots to check for activity.

On 20 you might catch the Maritime Mobile Service net around 14.315, not certain of its exact frequency these days but you will find it if you search. They would be happy to assist in an emergency even if you're not maritime mobile.
Otherwise as someone else said, just break a QSO in progerss. Normally

one "break" is a routine call, "Break-break" is something more pressing,
and a triple-break denotes an emergency.

Dick

Thanks Dennis. Actually, we're loaded to the gills with GPS and maps...we'll know exactly where we are. On my instruction sheet to keep near the radio, I'll be posting some basic radio operator instructions and other pertinent info such as our GPS coordinates, and the phone numbers for the closest sheriff's station, etc.. So, assuming that one of them can get through to anyone else, they'll have no problem directing law enforcement and/or search and rescue teams right to us.

Dave Platt's advice was great too. I figured I'd personally start at each of the bottom of the bands too...but I never even considered calling in the CW freq allocations...I'd imagine that could draw some great attention. I'm not sure how to best to train them on the CW/Phone band allocations just yet...I'll have to give that some thought...I don't want to make it too difficult, especially if someone's panicking.

Also, Dick Carroll wrote the "Break/Break/Break" protocol in an adjacent post ... I didn't know that ... thanks Dick!

If anyone else has anything to add, please don't hesitate. I'll be monitoring this thread until late Thursday evening and/or early Friday morning. You guys are fantastic! Thanks again...

Richard Clark, KB7QHC wrote:
"This suggests that knowing V/M and trying to translate that into a known voltage applied to a receiver is useless."

Don`t despair. As previously posted, Terman wrote:
"---rate at which energy is abstracted (power) from the wave is (volts per meter x effective antenna height in meters) squared, divided by twice the radiation resistance---."

That`s just E squared over R.

The effective height is the vertical component of the height. If the entire antenna is exactly vertical, the effective height is the entire antenna length (up to a point, anyway).

The volts per meter is the field intensity.

The denominator is twice the radiation resistance because a conjugate match is assumed to extract maximum power from the wave. The load is the radiatiation resistance of the antenna plus the matched load resistance.

Power available to the receiver is the total of the 1-meter antenna segments voltages in series squared, divided by twice the radiation resistance of the antenna. In microwave systems when this is measured, it is called the "received carrier power".

When you have an available power and it is losslessly transmitted through a system, all that`s needed is the impedance at any point to predict the volts and amps. If there are losses, it`s convenient to express everything in db to conveniently total the losses and identify the "level" at any desired point.

Best regards, Richard Harrison, KB5WZI

I am not familiar with the particular antenna, but the top section should be the 440 section. You will then have to readjust the 144 section. If all else fails, take a look at the simple plans for a dual band antenna on Arrow Antenna's site.

Basing you life on the vagaries of amateur radio is foolish, particularly since your companions are non hams. I would recommend you rent a satellite phone for the trip and use the 706 for fun and routine comms.

In the UK you could get bare copper from suppliers such as Westlake and the Scientific Wire Company... if you really want it. I agree with Reg, though: it's no big deal, so use what's easiest to find, which is probably enamelled.

However, there are various grades of enamel. 'Electronic' grades typically use the light-coloured polyurethane, which will start to crack and flake after a few years in the air. If you can, it's better to go to a winding shop and get the dark brown stuff, which is tough as old boots and will last forever.

Enamelled wire will almost always be soft-drawn because it is intended for winding purposes. For antenna use you need to pre-stretch it, or else it will always hang loose in the air. Ideally, lay out the wire below where it is to be hauled up, and stretch it there so you don't have to coil it again. The first bit of stretch comes very easily - when it starts to fight back, stop pulling.

Unless your want is to pick fly crap out of pepper, there is no difference between the two.

The whole subject is nonsense unless your worried about and inch or so difference on 75 meters. My guess is if you went to all the "experts" QTH's and looked at their antennas, you will find the determine factor was what they had on hand or what was cheaper at Home Depot.

No big difference. I think I paid about $19 for a 500-foot roll of
12-gauge THNN (?) stranded at Home Depot. Prices are no doubt a bit
higher at the local corner hardware store.

If you have a low resistance connection to the trunk lid then you are in ok shape for VHF/UHF. You need at least 19" of metal around the base of the antenna to form the "other half" of the dipole. With the trunk mount the drawback is that you only have that in three directions. Also, there is a capacity coupling to the adjacent fender that may help in the fourth direction. Very little capacity is needed at these frequencies. If, however, this is for HF then bond the trunk to the body with braid - use old coax braid. Your DC ground is back at the radio/battery.

I see no one has mentioned this reason for using insulated wire.

What will the loss of the bare wire be in 2 or 3 years?

By the way, I use bare aluminum electric fence wire, because it is cheap. You can buy a 1/4 mile roll at a farm supply store for under $20. When it goes bad or breaks, I just replace it. And the stuff is remarkably strong, a lot stronger than Aluminum clothes line. It is not as strong as hard copper, but comparable to soft copper.

Thanks, this is what I'm doing. I've got the wires cut and pretty much in place.

I'm after a balun so I can feed with coax. An internet search brought up a whole load of thin ethernet stuff (really useful to me!).

Where on earth (well, in the UK anyway) do you get 1:1 baluns??

Thanks,

D

well,
posting here will get you a couple of results:
1. you advise others not to deal with this person (let the buyer beware)
2. it may get his attention (and in means unwanted such as harrassment, etc).

also, if you have the originating snail mail address, send a complaint to the city atty general, and follow-up with one the county he resides in and the state. you might also send a complaint to the FBI (as this was an interstate crime it seems).

just some suggestions from one who has had similar experiences.

Technomage

Sure it is! It's a percent or so (some quite small amount) shorter,
thus has less copper for less I^2R ohmic resistance, so it must be more
efficient!

Now *there's* a purist for you! <g>

Jim Bolinger, N8EE wrote:
"What will be the loss in 2 or 3 years?"

The loss will likely be so near the same after the wire turns dark, brown, black, or green that any difference is difficult to measure.

Shortwave broadcast plants for transmission and reception that I`ve worked in and seen all used bare copper. Any performance difference due to tarnish was unheard of.

I had to install a 6-GHz microwave station in Port Sulphur, Louisiana near the Freeport Sulphur Plant. So happened, Freeport Sulphur was using the same microwave sets in their plant as we wanted to install. I visited them to inquire about precautions. No problem they said. No difference between bare copper and silver plate they said. We put our station in and measured its performance for years. Though the plumbing turned black inside and out within weeks, Freeport Sulphur was right. There was no measurable decline in performance of the radios.

Best regards, Richard Harrison, KB5WZI

Scott,

The gamma match is inherenty unbalanced, and does not require a balun, but uses a series capacitor. In commercial antennas, the capacitor is made by sliding a smaller tube inside a bigger one, with insulation in between. Unless you are copying something, this can make for complicated calculations. This is cheap to manufacture, most complicated if you just build one antenna. You don't want to do what is in the ARRL antenna book, which is to use an actual variable capacitor.

The T match is balanced, and requires a 4:1 balun. The balun is a NOOP, just 1/4 wavelength of 50 ohm coax. I have 2 antennas with this kind of match, works fine.

The hairpin match is balanced at 50 ohms, requires a 1:1 balun. Not sure how you would do this above 54 MHz.. The Hygain TH3MK4 tribander has this match.

Why not experiment. Since it is so simple, try the hairpin first, then the T. You don't have to put the antenna up in the air; for initial test, point the antenna straight up with the reflector a couple of feet off the ground. Based on measurements made on the TH3, the bandwidth gets a lot better once you get the antenna up in the air.

Is any match more efficient than the others? Does any of these devices affect the pattern in any way? I have a well built gamma match with sliding tubes on my yagi was looking for advantages of switching to a T match or Hairpin match - no matter how small the advantage.

Scott.

Just update your twit filters and move on...
usenet is like a cross country bus station in downtown
Saint Louis. You only want to 'interact' with less
than about 33% of the people you 'bump' into here.
It's up to *you* to do the selecting.

Jonesy

I get mine at depot also. But I paid $30+ for 500 ft of #12. But about
$19 for 500 ft of #14. You may have gotten #14. I used #12 for my
everyday dipoles, because when I put them up I wanted gross overkill
in wire. But I think I'll be sticking with #14 from now on. The #12 is
a good bit heavier. I don't think the extra weight is worth the small
difference in wire resistance. It's kind of like plain vs
insulated...I can't tell any real difference in comparing #12 against
#14. MK

I think you probably have a little better balance using the symetrical
matching device. Probably more critical for VHF/UHF than HF. Better
balance would mean less common mode problems. But both my 6m yagi and
my 2m yagi both use simple gamma matches. I haven't noticed any
problems with the patterns, and I haven't noticed any common mode
problems to speak of. I'd use a balanced device for a first class
setup, but I consider it optional. A gamma match will work just fine
usually. MK

Scott,

I have never seen any discussion of efficiency of matching arrangements like what we are discussing. Clearly, there will be some loss in a balun (probably not measurable in the 4:1, which at 50 MHz is the loss of 3 - 4 feet of coax). But the series capacitor in the gamma match will have some loss also. I am grasping at straws here, but the T match might have some advantage because part of it is at 200 ohms; so, any small resistance in series will be a smaller percent. I think Mark has it right. Besides, don't fix it if it aint broke.

Thanks for all the info,

I thought it was a simple question, but the many answers tell another story.

OK, so there may not be enough difference electrically. Weight is a good point. Static too.

I forgot about the static buildup when a snow storm approaches. Just as when the snow starts blowing. I saw this many times a few years ago, when I had my radio in my room. In the middle of the night it would wake me up or my brother, by hearing the static arc on the disconnected coax connector, or in the tuner. It it was visually impressive too in the dark !

The COM port connected to the VHF packet station blew out 2 times from the static. The ribbon connector was pitted badly by arcing to the computer case !

Use a longer piece of coax to feed the antenna, then at the antenna end wind 9 to 12 turns of it into a small "hank" about 10 inches in diameter,and hang that somewhere near the antenna feedpoint. That's your 1:1 "choke" balun. The number of turns would depend on the lowest frequency you will operate. I believe that 10 turns will handle the lower end of 80 meters OK.

Hi Rick.

True. I think the government agency is called the Commission for the Preservation of the French Language (or Culture ?). I know personally that they write very nasty letters to those not complying with Quebec language laws.

French required on the package. French had to be more prominent than English (or at least not less prominent). All manuals and documentation had to be in French (English was okay if necessary). It was easier to comply by ceasing to sell product into Quebec.

After a customer complained to the authorities, the agency actually sent officers into the ham store to inform them that they could not sell ham products unless they complied with the French language laws.

Richard Clark, KB7QHC wrote:
"This does not suggest what is actually captured tho`."

Terman tells exactly how to calculate the energy captured and transferred to the receiver.

Terman writes: "---Abstracted from the passing wave". That means power induced into the wire, and available to the receiver after half the abstracted energy is reradiated. The antenna is reciprocal so that current on the wire, no matter where it comes from, causes radiation. The antenna can deliver maximum signal to a conjugately matched antenna load. That`s Terman`s condition for his formula. A matched load means a 50-50 split between power to te receiver and power reradiated. That`s the best deal available to the receiver. Half the available power is better than none.

Terman`s formula takes care of the reradiation. The power abstracted from the passing wave available to the receiver is: E squared over 2R.

E is indeed the volts per meter times the number of meters in the wire.

The 2 in the denominator is because half the intercepted energy must be reradiated.

We have charts that give the radiation resistance for grounded vertical antennas. We must present the antenna with the same value of resistance. The antenna is a generator with an internal resistance, It is the antenna`s radiation resistance. It drops half the voltage generated by the wave sweeping by. The other half of the voltage is dropped across the external load resistance (equal to the radiation resistance). The power lost in the internal (radiation) resistance is reradiated.

The power in the receiver load resistance is E squared over R. This is the same power available to the input device in the receiver, less any loss between the antenna and the input device. Actual voltage across any input device deends on transformation ratio. It is power which must be conserved. Volts times amps at the antenna feedpoint equal volts times amps at the receiver input device if the loss between these points is negligible.

The field strengths predicted and measured agree very closely in most instances. Many times a calculation of the microvolts to be expected at the receiver using the field strength to be expected and the antenna system characterestics is made.

The signal is received in the receiver and an output indication from the receiver which is proportionsl the received signal strength is noted. A

precision signal generator is then used to replace the received signal and its output is adjusted for the same indication from the receiver as the received signal gave. This received signal level is then directly read from the signal generator`s calibrated attenuator. It works every time, and the often quoted field strengths produced at certain distances are true.

Best regards, Richard Harroison, KB5WZI

A simpler method I have used for years is to simply ground the shield at the antenna center, strip the shield and put the center conductor through a close fitting piece of tubing with a second piece over the first.

The center lead is not connected to anything, simply hangs out the end of the tubing. Now by adjusting the shorting bar and sliding the second piece of tubing back and forth you adjust for 1:1.

The capacitor is the center conductor, the insulation the dielectric and the tubing the second plate of the cap.

Works great, low cost and no fancy cap.

E is the volts per meter times the number of meters in the wire only if the wire is very short in terms of wavelength. For a quarter wavelength vertical, E is about 0.64 times the number of meters in the wire, and for longer lengths the calculation is more complex.

Of course, in the context of the original question, the wire will almost certainly be very short in terms of wavelength, so E will be as Richard said. Just be careful extrapolating this to other situations.

I watched the Navy change out hundreds of feet of 1/2" fiberglass rod on several CDAAs over the latter part of the last decade. It was used to guy the 100' tall low band backscreen poles on the antenna side. About 280' per pole, and either 40 or 80 poles depending on which version. Puerto Rico and Spain I saw myself, all the other FRD-10 sites probably also changed between my visits. Big dumpsters full of 1/2" rods cut up in short pieces. Replaced with Phillystran (sp?).

From those charts (or one like it at your neighborhood library) the
radiation resistance of a 1M vertical dipole at 1MHz is 0.0084 Ohms

>The power in the receiver load resistance is E squared over R. This is
>the same power available to the input device in the receiver, less any
>loss between the antenna and the input device. Actual voltage across any
>input device deends on transformation ratio. It is power which must be
>conserved.
(1 * M *196mV/M)ï¿½/0.0084 Ohm
4.57W
in regard to the model of the identical situation into a real load:
12 nanoWatt
If I replace that useful 600 Ohm load with the Ra, the model reports:
6.848 picoWatt
I wondered if the model was suffering from Iï¿½R copper loss,
so I set the model to zero loss:
8.179 picoWatt

What sort of transformer where you thinking of?

As a simple assessment of this vast range of power expressed through
math and model, I tuned up a local AM station near this frequency.
Using my longwire, the signal sat rock solid at 40 over S9. I then
switched to a 1M vertical dipole to observe an unsteady S4 signal. By
my calibrations, that is a 62dB variation. That is a relative
measurement. The absolute measurement is found relative to a known
level, S9. At 40 above, that represents a power of -32dBm.

What would my receiver SMeter reading present me at that magic one
mile? The number above sitting at 4.57W at high tide says I have some
60dB or more to go with my longwire, or 120dB with the short dipole.

That's a lot of halving of distances to a nearby radiator, and it
should at some point snuggle right up to it. Let me elaborate this to

suggest I was seriously off as to this being a local station at 40 over. Let's put it out 100 miles. I move in 50 miles and cut my losses by 6dB; I move in 25 miles and cut my losses by 6dB; I move in 12.5 miles and cut my losses 6dB; I move in 6.25 miles and cut my losses by 6dB; I move in 3+ miles and cut my losses by 6dB; I move in 1.5 miles and cut my losses by 6dB. Now, if my initial guess at the local station is actually true to within 100 miles, that range of variation only presents 36dB of signal boost available before my longwire is welded to the transmission tower. This says nothing of the short dipole and is a far cry from
(1 * M *196mV/M)ï¿½/0.0084 Ohm
4.57W

V/M remains an obtuse and impractical technical unit and seems suitable only for physicists or fcc lawyers.

Hi Fox,
download and run SELECT_1.EXE from
http://www.btinternet.com/~g4fgq.regp/page3.html#S301"
It is probably the simplest solution for matching a receiver to a
longwire antenna and improving its selectivity - a coil with two taps
(the program designs it) and a variable capacitor.

Extensive testing a few years back with "R5" CC verticals showed NO
DIFFERENCE between ground mounts, roof mounts, and tower mounts to
in excess of 100 ft. relative to signal strengths.

Relative to safety, keeping the radials and hardware away from
eyes (not tall enough or too tall pole ground mount) is something
to consider. Other than that, keep the coax short but your
body out of the strong EM fields.

Many thanks Dick.

So is that all a balun is when it's not operating as a matching transformer?
A choke.

It presumably just stops RF going back down the outer sheilding of the coax?

Would be useful if there were a device which actually measured any RF doing
that, so you could check the efficiency of the balun and adjust it
accordingly wouldn't it?

Put a number of turns of wire on a ferrite toroid slipped over the
coax. Rectify the resulting voltage and measure it with a DC voltmeter.
Relative common mode current measurements are very easy.

Great article coming in the Q.S.T. next month.
Larry a guy from W8 land is writing about computor
interfacing of antennas, and he is SHARING information
as to where to get the parts without personal gain
Thus we will have an article that helps all rather than
pages of circuits most could not build.
At last we have somebody who has come along and
shared his expertise in an area that most members
of the antenna groups have a thirsting for.
(Sharing just like the hams on this group)

At last I have a good reason to purchase a Q.S.T.
Hope hams will give a thumbs up to Larry and Q.S.T.
As a priper go to the stepper company page and
then go to the Links. I have read the link several
times and now can't wait for Q.S.T.
My e mail address is now aunwin@K insightbb. com
Remove capital k and spaces. I don't know how to
change the e mail change for these postings.
Instructions by E mail would be appreciated
Thanks

Source record: 132854

A transmission line of any sort behaves as a SINGLE antenna wire in respect of any unbalanced current which flows along it. Therefore, in general, it has standing waves on it - and so like any other single wire - it radiates. By reciprocity it also receives.

A choke does not necessarily stop radiation from (or reception by) the feedline. In some circumstances it may enhance it. It merely ensures the current standing wave is a minimum at the position the choke is located. The current maximum of the standing wave is shifted along the line to another location 1/4-wavelength from the choke.

Depending on whether the new locations of max and min are more or less favourable the line will more or less continue to radiate. But radiate (or receive) it certainly will !

Whether the choke serves the intended purpose depends on how the unbalanced current is induced, coupled or injected into the line from the main antenna and on the length of the line in wavelengths. Specially with multiband antennas it also depends very much on frequency.

To check the effectiveness of a choke it is necessary to measure unbalance current over a length of line at least 1/4-wavelength long at all frequencies it is intended to operate on.

To check at one place immediately adjacent to the choke will be to delude oneself, because there, a current minimum is guaranteed.

Sure does, thanks for confirming my point. Which is, in ham radio, as opposed to commercial installations which typically remain on a single frequency,(or switch to another resonant antenna when changing frequencies),we routinely employ wide frequency excursions within a single band. We need to understand that some loss is just another acceptable part of the landscape. Whether or not one matches at the line input or at the antenna feedpoint, the antenna will NOT hold 1:1 across the entire band.

So what do you want to do, accept the mandatory loss you WILL have, or go to elaborate lengths to eliminate the mismatch loss in coax, which is almost always low at HF due to the use of relatively short lengths of cable of low loss at al most all hams use?

Even if the loss amounts to something significant, such as 6 dB, it can be perfectly acceptable under the instant circumstances. In fact, I'd wager that many hams routinely incur losses on that order without realizing it. I know I once did-

When it was new on the market, before it was widely realized that 9913 was so vulnerable to water contamination, I installed a 150 foot run of low loss 9913 cable for use at HF. Of course, over a period of several years, it became contaminated with moisture inside due to the ingress of humidity such that it eventually became unusable. Realizing what had happened I decided to check it to see what loss was actually involved when it got to the point that it wasn't producing contacts anymore.

Inputting 100 watts at the transmitter, I placed a Waters terminated wattmeter at the line output. Even on the 10 watt scale, I could detect NO rf energy arriving at the antenna. The meter didn't flicker perceptably at all. But tests on 75 meters with stations 50 and 100 miles away revealed that those stations could hear me on SSB, although they couldn't copy what I was saying due to the extremely weak signal. Close to 100% loss, whatever dB level you want to assign to that. The radiated power surely was in the the low tenths of a milliwatt, though I had no covenient way to measure it.

The point is, even with severe mismatched (and matched) loss, that coax was useable -and was used- far beyond any level of what we would consider to be acceptable loss.

I stand by my earlier comment that the knowledge and (eventually) experience to understand what is happening and to sort all this out is what hams need, not a perfect match at all times, which they'll never have except at resonance anyway. Knowledge to understand the causes of loss and to determine if and when a given amount of loss can be useful and acceptable.

If I can assist in some newer hams gaining the insight leading to a experience at an earlier stage than I was able to gain, I think it's a worthwhile effort.

Richard Clark, KB7QHC wrote:
"From those charts (or one like it at your neighborhood library) the radiation resistance of a 1-meter vertical dipole at 1 MHz is 0.0084 Ohms."

I don`t have a handy chart so I`ll obviate the need of a chart.

Suppose we are at 1 mile from a 1 KW station broadcasting on 1 MHz.

The voltage induced in my 2 meter long vertical antenna is 0.392 volts.

In a 1-meter vertical, the volts are 0.196 volts. The power in a square meter of the wave is: (0.196 V) squared divided by 377 ohms, or 0.102 milliwatts.

With a 2 meter long antenna, say I can grab the wave power in 2 square meters of the wave. Half of this power has to be returned, so that leaves 0.102 milliwatts that may be applied to the load.

In a lossless transformation (an impossible dream) the voltage across any receiver input resistance is simply the square root of PR. Say the receiver input is 50 ohms. Volts across 50 ohms are: 0.071.

At 1 mile from the 1 KW transmitter, that seems a reasonable ideal. Loss will pare away some of the voltage, so less than 70 millivolts would be expected. At greater distances, the voltage to te receiver is inversely proportional to the distance. At 10 miles, only 7 millivolts would be expected across that 50-ohm input if 70 millivolts were the signal at 1 mile.

Best regards, Richard Harrison, KB5WZI

A 4:1 SWR on coax is good? Must be some new kind of good you're talking about there. 1.4:1 is O.K. but 4:1 is no way 'good'. Throw away the coax and feed it with ladder and you'll have a good antenna. I really can't see any reason to recommend a G5RV to a beginner.(or anyone else). Your transmission line tuner is fine, however.

That's one version, but of course it doesn't transform impedances.
Sometimes a 1:1 transformer might be desirable instead of just a
decoupling the outer shield. But that decoupling does provide balance
deending on its efficiency.
It can be as simple as an RF choke on the outer sheid, but under some
conditions it doesn't keep RF off the shield. See Reg's post:

Not sure about the spacing, but for linear polarization they should all be fed in phase. NEC would help optimize the spacing, I think.

One method for feeding them is to cut some 72 ohm coax to be an odd quarter wavelength (1/4, 3/4, 5/4, etc.) long. Connect one to each dipole (with a balun of some type). Connect the other ends of the 72 ohm coax together in pairs, which gives a 50 ohm feed point. Then connect these 50 ohm points in pairs with more 72 ohm coax. This should all be in the various antenna books, usually under 'collinear dipoles', but should also work with crossed dipoles.

Well, would you believe "not bad"? :-) The loss in 100 ft. of RG213 with an SWR of 4:1 would be about 0.01 dB higher than the matched line loss according to the chart in _The_ARRL_Handbook_. On 160m, the loss increases from about 0.22 dB to about 0.23 dB and on 75m, the loss increases from about 0.32 dB to about 0.33 dB. Exactly how does one measure that extra 0.01 dB of loss caused by an SWR of 4:1?

What's up with changing to a 2 meter element? Let's not play
monkeyshines now, simply stick with the original 1 meter
specification:
P = Eï¿½/R
P = .196ï¿½/0.0084
P = 4.5W

Now let us consider the implications of this with a simple math
exercise involving nothing more than addition (OK repeated addition,
simple multiplication). We face the delirious prospects of this
bounty of four and one half watts to a load placed in the middle of
one meter of wire located one mile from the transmitter.

I place a similar one meter loaded wire at every degree surrounding
the tower.
P = 360 * (1M * 196mV/M)ï¿½ / 0.0084 Ohm
P = 1627W

What we have now is a truly remarkable sort of electronic fence that
completely absorbs every watt of output (by 163%) from the emitter.
This fence stands only 0.0033 wavelength tall and its pickets are
evenly spaced 92 feet apart (smaller than the Maginot or Siegfried
lines but vastly more powerful!).

I suppose this is why AM stations are located in the swamps. If they
had any form of listening audience within a mile, they would have no
audience beyond that same mile. Actually, they wouldn't have many
listeners within that same mile either given the 163% absorption. So
it seems the AM industry needs a new technical unit that more
accurately reflects the mission of AM (getting out to the listener).
I would nominate the term "snipe" (as in snipe hunt).
snipe = 0.6135 * 360 / 1KW / mile

snipe : listeners per KW at no more than 1 mile range
for this exercise we find the snipe value at 221 listeners/KW/mile
total (221 listeners exhaust the entire KW radiated). I hope their ad
revenues justify their existence.

Richard, this fence works far better than those faraday cages.
Actually, this sounds like Tesla's work on radiating power to
subscribers. After-all, with several many light bulbs with 1 meter
power leads, this seems sufficient to light the average home quite
well. We should all be so lucky to live near an AM station.

Dare I say this is cheaper than nuclear power (and that's free!)?

This makes me wonder, what would happen if I simply chopped my fence
down by 90%?
P = 360 * (0.1M * 196mV/M)ï¿½ / 0.0000877 Ohm
P = 1577W
Well, things don't look too good, I lost 3% of my absorption - but
still quite remarkable as a fence 0.00033 wavelength tall with pickets
92 feet apart.

Gee, with a world of 10cM leads so easily available, its a miracle AM
out beyond 10 feet works at all. As for free radiation powered light
bulbs, this shortening of leads is a dramatic breakthrough in
efficiency. I look forward to the day when they shorten the lightbulb
power leads to 1cM so I don't have those dangling wires everyone is
tempted to jerk to turn off the light (it killed the last guy when he
tried it).

Obviously, the technical usage of V/M is as useful as transmission
line capacity is useful to an ENRON power broker: you can apply it to
any balance sheet certified by Anderson Consulting. Then, of course,
there are the modelers such as EZNEC that give much more realistic
values.

Whether a current balun (common mode choke) shifts the current distribution on a line or reduces it along the whole line depends on the length of the feedline, what its ends are connected to, and the position of the balun. In cases where the current distribution is simply shifted along the line as Reg describes, a second balun placed about a quarter wavelength from the first will reduce the current along the whole line. The reason this works is that there's no standing wave pattern that can exist when there are two high impedances with this spacing. Of course this is most effective only on one band, and might not be effective on another band if the balun spacing is close to an integral number of half wavelengths on that band. Fortunately, multiple baluns don't seem to be necessary very often in practice.

> Relative common mode current measurements are very easy.

If you do this, be sure that you put a fairly low resistance (say, 50 or 100 ohms) across the winding. Otherwise, the toroid you're using for measurement will insert a significant impedance itself, changing the common mode current when you insert it. When terminated, the insertion resistance will be R/(N^2) where R is the terminating resistance and N the number of turns, assuming you use a 70 series or type 43 core.

Actually, quantitative common mode current measurements are just as easy as relative ones. The current on the feedline = VN/R, where N is the number of turns on the core, R is the resistance connected across the winding, and V is the voltage across R. If you use 50 ohms for R, you can connect R and the detector at the end of a piece of coax, and put the core some distance from the detector. N = 10 and R = 50 is a good combination. This technique, with a dual trace scope for a detector, also works well to measure the currents in phased arrays.

Hi Doc,

Bated: stilled, stopped (you weren't really holding your breath were you?).

Baited: suckered, cheated, lied to (I repeat, you weren't really holding your breath were you?).

Still and all, either definition applies to this anniversary of the abysmal trouncing that fractals received. Halloween is also an appropriate time to dig up those corpses and dress them up for sale (or is it sail?) or peer review at the next comic book convention.

No nefarious motive. I don`t have a confirmation of the radiation
resistance at hand, but I do know the resistance of free-space, it`s 377
ohms. I used a 2-meter length of wire because 1/2 the power abstracted
must be given back. Thought that fewer numbers on the page would
simplify the explanation.

My original response was:
"15 to 20 feet is usually plenty of antenna."

I never dreamed that simple and accurate statement would need such a
tedious defense.

True story, not a "rumor":

On a vacation trip, we had planned to visit Montreal and spend some time (and money) there. As I drove up from New York state, I found that the highway signs were in french only and did not include english translations.

I didn't have a clue as to what those signs meant. No high-school french here! Yet, I was responsible for knowing the rules of the road as spelled out by those signs. Made me nervous, to say the least.

I could see Montreal in the distance as I turned and headed back to the USA. Never been back to Quebec.

OTOH, I have since been in ALL other provinces of Canada and have spent months of vacation time and thousands of $ there. The other provinces often provide the vital info in both english and french. Not, apparently, Quebec. I won't visit Quebec again. Maybe that is what they want?

I have a spool of wire marked "Belden 8009 Solid 14 gauge Antenna Wire, 500 feet". It has a date code 197_ so as late as the 70's Belden did sell the stuff. I don't know if they still do. Has dark enamel insulation. I bent the end of the wire and it seems stiff so looks like it may be hard drawn. Don't remember where I got the half-spool and haven't used it, so I don't know how it holds up. Think I'll put it to use and see.
If it's still on the market I bet it's not $14 a spool!
For what it's worth to anyone.

Dick

This is why I say that hams all too often fixate on keeping the SWR 1:1
at the expense of all else without understanding what effect it actually
has on THEIR station.
I catch a lot of flak for that but it remains true.

Doesn't seem to be available these days... 8009 doesn't appear to be
an item in their on-line catalog.

Closes thing appears to be #8073, a 14-gauge solid-copper magnet wire
with a synthetic-resin enamel insulation (Polyester/amide/imide).

>If it's still on the market I bet it's not $14 a spool!
>For what it's worth to anyone.

Newark wants between $20 and $30 per 80-foot spool of the magnet wire,
depending on how much you order. Ouch. Ordinary household wire seems
like a much better solution, at $15/500' - you could replace an
antenna several times, a few years apart, whenever the plastic
insulation breaks down, and still come out ahead.

Hey Lou, since your charts that allow "for modification to 10M or other freqs." are obviously intended for use by licensed hams, you might get more business if you posted this in ham newsgroups. Doncha think?

> 'Doc

My understanding was that it was to be in November Q.S.T.
There is quite an interest in operating antennas remotely
by computor for those who cannot install a tower at the
home QTH. computors are also being used for many other
things especially in contesting,monitoring band activity
etc. It is extremely usefull for interfacing with motor
control of variable capacitors and inductancies.
When you think of it Q.S.T has not presented any articles
showing how to control stepping motors for loop antennas
which appear to be of great interest these past years,
or even talked of why loop antennas require more than
one loop to obtain full H.F. coverage.
I would particularly like an article for manual control
of tuners at the tower top without pages and pages of
home brew circuits but by using simple stepper drivers
which are extremely cheap thease days.
Ham radio and radio communications used to be up to date in
ham stuff but unfortunately both are now gone.
I suppose that such articles in Q.S.T. is symbolic of what
one would expect in April, but to attract newcomers to ham
radio we cannot afford to rely solely on articles of yesteryear,
or the assumption that all have the time to homebrew complex
circuit boards at work while the boss is not looking.
Take the time to look at the links provided on the
Steppir page, all of which provides a modern aproach which
is in tune with hams of today.

>
> Tam/WB2TT

Absolutely!
The aluminium will disappear quickly and the copper stay. Humidity and dirt
from the air is enough to start the corrosion process, and a coating will
only enhance the problem in spots where the coating is not complete.....and
such imperfections will always be present.....
If you want to mix materials, mix only with good stainless which is
(practically) inert, or prepare for the fact, that the less electro
chemically resistant material will be dissolved.

1009. How to fasten Coax on crank-up tower

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-18 15:04:11 UTC
From: "Tim W. Henry" <both@pcisys.net>
Message-ID: <ur08ekh0pgb23c@corp.supernews.com>
Source record: 132898

I am putting several antennas on a crank-up tower. The tower comes with guides to keep the coax & control cables from flopping around. The entire weight of the cables hangs from the top of the tower where they are fastened. Is this OK, or should I fasten the cables to the guides to support their weight at the top of each section of the tower.

Your help will be appreciated,

Tim -- AB0RI

1010. Coaxial Inverted "L" data

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-18 15:07:02 UTC
From: Dave Heil <k8mn@earthlink.net>
Message-ID: <3DB02370.A8DF318E@earthlink.net>
Source record: 132900

Several have written asking for more detailed information on the coaxial inverted "L" antenna for 160m. The article I wrote of earlier was written by Ted Cohen N4XX and appeared in the January, 2001 issue of CQ Magazine. It references an earlier article by Rollman from the August 1984 issue of CQ.

Ted's antenna uses RG-8X (or "mini") which has a velocity factor of .78. If RG-8U or RG-213 were to be used, its velocity factor of .66 would have to be taken into account in coming up with dimensions. Thus the 104 foot piece of cable would become an 88 foot piece. The overall length of the antenna would remain 124 feet. Note that I found it necessary to add about three feet of cable to the 20 foot section to move resonance to 1.850. The formula for determining total antenna length is 230/F (where F=frequency in MHz). The formula for determining the length of the section containing the 1/4 wave shorted stub is [(492)/2] x vf/F (where vf=velocity factor and F=Frequency in MHz. Those formulae will aid in scaling the antenna for 80m.

The antenna is made up of a 104 foot length of the RG-8X fed at the bottom by *feeding the shield* and grounding the center conductor. The far end of the 104 foot piece of cable is shorted. At that shorted point, another 20 feet of cable, shorted at *both ends* is attached.

The inner conductor of the 104 foot section of cable acts as a 1/4 wave shorted stub presenting a high resistive impedance to the feed point at resonance. The off resonance impedance changes in a way which increases bandwidth.

While I've found the antenna to cover the 160m band at under 2:1 SWR, remember that the U.S. band is only 200 KHz wide. The same results will not likely be achieved on 80m where the band is 500 KHz wide. One individual asked about 40m. On that band an inverted "L" of plain old copper wire is likely to have an acceptable SWR across the entire band without resorting to the trouble of fabricating a coaxial inverted "L". My sole contribution to the constuction of such an antenna is to recommend the use of a pulley with a fairly large wheel diameter at the "L" point where the antenna bends. I tie the pulley to an insulator attached to the tower. It prevents a sharp radius at this point and should contribute to a long life for the antenna.

While the vertical portion should be as high as possible, don't worry if you can't get the vertical portion up higher than forty feet or so. Mine runs sixty feet vertically and is perfect for my situation where I have two towers spaced not quite far enough apart to allow placement of a traditional inverted "L" which would have a total length of 165-175 feet (with series capacitor).

For the "horse hockey" crowd--the skeptics who are quick to dismiss things they've never attempted--the antenna works. I've had my coaxial inverted "L" up for about a year. In the very first week I broke a pileup on a 5W in Samoa while running 100 watts. I worked VP8GEO with ease and was one of only 26 eight-land stations to work ET3PMW on 160m. I'm not saying that you'll obtain the same results. My being out in the country atop a high ridge and having a couple of thousand feet of radials beneath the antenna help a bit.

The antenna hears noise as well as any other 160m antenna I've ever tried but it seems immune to precipitation static. I'd guess this is because it is covered in vinyl. For much of the several decades I've been on top band, I've been a proponent of omega matched towers. My present circumstances preclude such an antenna because one of my towers is a crankup and the other is fitted with a Hazer tram system. Thus I decided to try the coaxial inverted "L" because it met a need. The fact that it allows me to operated anywhere in the band without the use of a tuner is simply a bonus.

Finally, the RG-8X version of the coaxial inverted "L" will take the maximum legal U.S. power.

Dave Heil K8MN
Cameron, WV

I know very well that Canada is bilingual. I was just joking about the fact that somebody could be astonished that road signs are in French in Quebec. The rest is just kidding like Tdonaly did. BTW I am French speaking but I (try to) speak 4 languages and I am living in a trilingual country. So for me it's quite normal to adapt to the local language when I am traveling, isn't it? And after all, French is not so far from English for not understanding road signs.

Source record: 132902

Arthur's description of the article is so "improperly titled" that no one can find it. There is an article in the latest QST that describes an Internet Remote Based Radio system. It allows you to run a complete HF station remotely via the internet and make it available to the public (subject to some stringent security).

What this gives you is access to a ham radio setup (including antenna pointing and switching) if you live in a restricted area and can't put up antennas, etc.

The whole process looks tedious to me, but I live in the country and can put up whatever I want. It still is quite a technical feat they have described and made operational.

The article is not about computer interfacing of antennas. It is about Remote Operation of an entire Ham Station via the Internet. Yes, antennas are included (pointing and switching), but they are hardly the focus of the article, hence, nobody could figure out what the heck Arthur was talking about. It's there....just not quite titled by the subject that he was referring to.

Tim,
I think I would use the guides/coax arms. They
do serve a purpose, and you already have them, right?
Reducing the weight hanging from the coax connection
at the top can't do anything but help the life of the
feed line.

The only problem I've found with using 'thhn' single
wire for antennas is that the insulation (the clear part)
starts to 'shed' after some time exposed to the sun. If
you can live with a 'mangy' looking antenna, it shouldn't
be a problem electrically.

It's a lot easier than trying to decipher the "international" symbols that I see. Some of them are so obscure
that I have to pull over and look them up.
My name is French, and when I'm in France, they seem to think I can speak french, like it was genetic.
Unfortunately I only speak american and that badly.

1017. 73 Magazine Article Help Needed September 2002 Issue

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-18 20:19:15 UTC

73 magazine had a three-part article in the July/August/September issues by K8ZOA on a VLF to HF loop receiving antenna that I want to build....I've got parts 1 and 2 but missed the Sep issue. Anyone out there have that issue who could make a copy or scan the third part from the Sep issue for me?

Thanks very much in advance!

Dino KL0S/4

hasan,
thanks for clarifying that. It makes a bit more
sense now, although, I don't see how the 'security'
part of running a remote station like this can be
done reliably. I think it would be much more
trouble than it would be worth.

Art,
I wonder how the 'control operator' is going to
do the 'security' needed for that kind of set up.
Not too sure you really could be sure the 'remote'
operator was qualified to use the thing without a
lot of extra work.
you might check the back issues of QST, I think
you will find several articles about stepper motors
and their use in amateur radio. I can remember seeing
several articles, but it's been a while. The same
holds for the loop antennas, there have been a number
of articles, you just need to find them.
As far as attracting new people to the hobby, I just
don't think that's as big a concern as some people make
it out to be. Those who are interested will find a way
into the hobby, those that have to be coerced into it
should wait till they have a genuine interest. It seems
I remember hearing about all the people just waiting
till the code/theory requirements were made easier so
that they could get into ham radio. I haven't seen a
large surge in the ham population, have you? Or, maybe
they're just waiting till they can get a license with
a couple of box tops?

Oh, they're there. They're just all Shack-On-The-Hip appliance
operators. 2M FM once was passably useable - years ago.
I find nothing of substance there anymore and have forsworn its use.

Were I to do it, I'd probably build the control mechanism to "look like" a secure Web server, using SSL to encrypt the control link when passing over the Internet. Access control and authorization could be handled as a Web security domain (via .htaccess or a similar username/password system) or by the use of individual client-side PKI security certificates.

A secondary set of ports (either TCP or UDP) would allow access to the audio channels, PTT control, etc., and access to these ports could be restricted via IP firewalling, with the firewall being managed automatically by the Web-based control mechanism.

Just to set the record straight, my article was scheduled for the November issue, but I got an email from ARRL saying that it is being rescheduled for another issue in the near future.

The article that's in the November issue was written by some guys I met on the TRX-Manager reflector...it's been scheduled for longer than mine was...I think they wanted to put us together in the same issue but ran out of space.

Anyway, my article describes a remote base system that I'm using that controls the rig, rotator, and a software interface panel that reads and displays up to eight analog voltage parameters at the remote site, and controls up to 16 relays...4 of which can be used to control a Top Ten Devices Band Decoder/Antenna Switch.

A major feature of the setup is that no computer is required at the remote site. The control is secure because I use direct dialup over ISDN, using one of the 2 channels for audio and the other for control...passwords are required to dialin. Where I live, ISDN is readily available and is actually cheaper than two analog phone lines, and provides two high quality digital lines. The audio in this arrangement is far better than any internet type of audio...which I require because I use PSK and MFSK, as well as cw and SSB. Using a standard phone line for control, and VHF/UHF link for audio would also work. There are more details on my website...www.telepostinc.com/n8lp.html

The antenna control software will be part of a future article I'm working on that will describe a software tuneable minibeam I have built. The antenna is pretty much done and tested...the autotuner works, and the software is done...I just need to perfect the phase detector that monitors reflector phase, so that it will work reliably under SSB use (wide power swings).

The antenna will be easily duplicated with standard hardware, plus both off-the-shelf boards and a little homebrew construction for the controller/serial interface. I will also probably make a kit available for those who want something more turnkey.

The project is close enough to being finished that I can state pretty confidently that it should not be placed in the April issue ;-)

73,

Larry N8LP

The US has 3 classes of license being issued now. Technician good for 50 mhz and up. No code needed.
General good for all bands but restricted as to frequency segments in each band below 50 mhz. Code at 5 wpm needed for General and Extra.
Extra , the highest, good for all ham privilages.

You can go to www.qrz and see a practice test.
The test is a question and you get 4 possiable answers . You pick the best one. You can get a book from many sources that contain the exect question and answers. Forgot the precentage of answers but think that it is 70 % correct.

Will Chip step up to prove you wrong this time? He seemed quite
sure of himself in his last statement about his methods; to wit:

"We do not use a conventional genetic algorithm. That would be far,
far too slow, and also impossible to use for complex structures, as
the genome would be astronomically large.

"What we have is not shareware, nor purchased; it is proprietary.

"The FOM has to be coded; normally this is an easy task.

"How the engine works is not important; what is key is its ability to
identify something 'better' than what's out there. It is basically a
black box for this exercise. It is the I/O that's of interest.

"You may wish to use shareware to run your own exercise, although I
suspect that it will be 3 orders of magnitude slower, and possibly
more."

Dean, I wish you success and my curiosity is aroused.

What sort of exam is your USA Full Class A Ticket ?

Leaving aside the non-technical stuff, is it an exam which requires plain English 'written' answers to questions, or does it require a tick to be placed in the little box provided alongside each of 5 possible answers offered to candidates by the examiner, ie., the box which is deemed by the candidate to be alongside the most correct of the 5 answers?

Over here we have the occasional situation where the examiner (old wife?) is unable to provide, amongst the 5 possibilities, the correct answer to his own question. That's just an opinion of course. <grin>

From a reasonable number of questions covering a number of topics it is then possible for marking to be done by computer which calculates whether or not the candidate's score is above or below a predermined pass or fail level.

Immediately following the exam it is also possible for the computer to adjust the pass/fail level such that only a certain fraction of candidates are successful. Or that only a certain number of candidates are succcessful depending on how large large or small the national radio amateur population is deemed by the licensing authority to be optimum. We then have a competition not between candidates and the examiners (who set the questions) but between the candidates themselves! What the questions is not relevant.

I have no idea of how things operate in the States. I don't have much of an idea of how things operate in the UK. But we all have our own individual ideas on how to get kicks out of the hobby.

Any other comments on where the computer age is leading (or is it dragging) us ?

I'm wandering around on South Eastern Australian vintage red tonight. It's supposed to cleanse the arteries. Anyway it takes my mind off oil.

Hi all!

I'm about ready to mount my HF6V vertical and after reading the directions, I'm looking for somebody who's had some experience with this antenna since I'm trying to determine which items to put in order on the ground mounting screw. Should the Q-coil go on first, then the line from the radials then the briaded side of the coax? Is another order better or does it matter at all? My view is since it's ground, it shouldn't make much of a difference, but looking for s second opinion.

Jeff

Maybe, but I have encountered a LARGE highway sign a few miles East of Montreal which appears to be a very important warning, presumably of some safety hazard, and neither I nor my francophone passenger could even hazard a guess as to the message it was trying to convey.

A while back while driving through Montreal I determined that the electronic signs were advising me that the road ahead was flooded - turned out they were saying traffic was flowing! French can be quite far from English at times.

Dave

I saw a Spanish sign in a hallway the other day. I thought at first
it said that someone had urinated on the floor.

Hi Chip,

Not sure which system his was. Was it the one that was written up in QST a few years ago?

Better is relative. I know some of the systems in the past have been based on the Kachina rig and aux boxes...which are no longer. I think AES used to make an interface that some people used also...but don't hold me to it.

I had several things in mind when I did mine.

1. It had to be generic...be adaptable to any rig, any control/logging/PSK software, any network connection. By converting the equipment serial ports to TCP ports and plugging all the equipment into a router...all that is necessary to access the equipment is to plug the router into a TCP/IP network connection of some kind. It could be internet, but I prefer direct dialin. At home, the equipment ports appear on the station computer as "virtual" com ports, which can be selected with any program that communicates through serial ports. So you are really seeing the equipment, piece by piece on your desktop as though it was plugged into a serial port on the back of your computer. It also lets you control a rig from another rig's front panel instead of using software, for certain rigs.

2. No computer at the remote site...most systems today use a computer running a program like TRX-Manager...usually with pcAnywhere or similar to control things. Remote desktop control is too slow for PSK displays, plus you have the hassle of maintenance on the remote computer if it needs rebooting, etc. My whole setup consists of a multiport serial device server, an ISDN LanModem/Router and my A/D-relay box. Three boxes running off of a deep cycle battery.

3. Totally secure. That led me to landline control, with password protection for both audio and control lines. The LanModem provides password protection for the control port, and the audio hybrid has password protection for the audio port...plus DTMF tone control of 8 relays at the remote site as backup control in case the software control link fails while transmitting, etc. as required by FCC.

4. High quality audio...this is why I settled on ISDN. It's a dedicated dual 64kbps line, with extremely low latency (it's used within most central offices for switching and connecting all phone calls, so you're used to hearing it when you use the phone in terms of latency). NetMeeting and the like are marginal for latency. Also, since I send PSK tones for transmission, the transmitted spectrum would be compromised with lesser quality lines. The quality is good enough that I can send keyed tone for cw, so that I can use a paddle instead of a keyboard for cw if I want.

There is a link to a help file on my website near the bottom of the page
under Remote Control that has a block diagram and further info.

Larry--

Is this a better system (I presume) than what Roger Strauch was using out on the west coast a few years back?

Hello, I have a interest in learning more about sloper antennas. The internet doesn't have much in the way of homebrew plans for such a beast. I found a site showing a 3/4 wave Zepa Sloper but it doesn't give the formula for the 3/4 wave wire. I would love some feedback on this topic. 73

Hi The sloper is a good antenna it gives a little gain in the
direction of the slope especially if mountend against a tower of metal
mast. but is worth doing in any event.. espesially good antenna on 40
meters and below... not magic to it , if you have a tower of metal
mast- use a quarter wave sloper-- 234/freq mhz=length mount it so the
angle to ground is about 45 degrees. If you do not have a metal mast
you can use a half wave diople and slope it 45 degrees.. 468/fMhz=
length in feet. 3/4 and 1 wave slopers will also work.. 3/4 wave
702/fMhz=length in feet. full wave 936/fMhz=length in feet. I've
used all of them to good account in the past. give it a try.
73 Dave
CQ had a series of articles on sloper last year I belief you might
check with your local library see if they could get them for you.

Jeff;

The described sequence is fine and does not matter electrically.
Just be sure to install as many radials (up to 60) as possible for
good low angle DX work.

Good luck,
Jim, K4SQR

There is a God, I would like to see what happens when YOU mount your antenna. Exactly what pleasure does one derive from that? You do the mounting as "I" will push a few hundred watts through it. That should brighten your day.

Seriously Jeff, check the assembly instructions.

>roof (flat roof) in a bucket of concrete.

Quoting from the Sigma 5 manual, "The Sigma 5 should not be placed too
high above ground. If vertical antennas are placed too high, the
energy splits off and creates a high angle lobe that actually has more
energy than the desired low angle lobe. As the vertical is raised,
the height above ground changes in terms of wavelength and the bands
are not the same (i.e. 10 meters changes twice as fast as 20 meters).
The feed point will also change, as the higher heights lower the feed
point impedance...."

I've just ordered one of these critters for use at the beach condo
until the CC&R police shut me down. Since a couple of my neighbors
have ship to shore verticals mounted permanently to the side of their
units, I'm hoping that my intermittent use of the Sigma 5 will be
either unnoticed and/or ignored.

1047. Tower base bolt corrosion prevention ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-19 15:26:44 UTC
From: AA6QN <aa6qn@excite.com>
Message-ID: <3DB179B8.E8584B93@excite.com>

Not sure if this is the right forum for this? Here goes, I am in the process of rebuilding a self supporting tower to replace an older fixed guyed tower. The concrete foundation was layed several years ago that made use of 1 inch dia high tension J-Bolts. I noticed that there was corrosion right at the cement level on the bolts. I know rust never sleeps :-(

I am having a adapter plate made for the replacement tower but wanted to perform some kind of corrosion prevention on those bolts prior to setting the plate in place. especially at the point where the bolt leaves the concrete.

I was thinking about the old sailor method of using grease between the adapter plate and concrete but did not want to trap moisture. Was also looking a LPS compounds the dry to a hard surface.

Construtive idea's are welcome. Tower safety starts at the beginning.

Best Regards, John

John, AA6QN wrote:
"I am having an adapter plate made for the replacement tower but wanted to perform some kind of corrosion prevention on those bolts prior to setting the plate in place, especially at the point where the bolt leaves the concrete."

The concrete never completes its chemical reaction. There is always free water within the concrete available to react with the cement. Concrete placed by the ancient Romans is still reacting and getting stronger every year.

John missed his chance to simply protect his J-bolts with a hot-dip galvanize treatment before pouring concrete around them. The J-bolts are in a perpetually damp environment

Galvanize the adapter plates before installation. Bury zincs around the tower bases and connect them with the rusting bolts. The zincs in the soil will slowly eat away and will in time require replacement. But, rusting of the bolts will stop. Minimize contact with the soil of copper wire connections for the zincs or the cathodic protection current would be mostly between zinc and copper instead of between zinc and steel.

Best regards, Richard Harrison, KB5WZI

Antennas are scalable to wavelength. If you change all the dimensions by 440/640,
you should be very close.

Hi OM,

The only challenge I put up was for the past (and defeated) fractal
Champion be applied to this "optimization." That way there was no
doubt about the pedigree - nor the outcome.

One might suspect such closely guarded details of being jimmied into a
favorable light, but not here. Even the most basic announcement of
pass/fail carries embarrassing admissions that need no figures. :-)

Conundrum:
Optimization succeeds - which in one fell swoop destroys
the claim that fractals are the most optimal form;

Optimization fails - which in one fell swoop destroys
the claim that fractals are the most optimal; and destroys the
claim that optimization works (it could't deduce the 6 triumphant
challengers which felled the fractal!).

To answer your question: Don't anyone bate their breath in
anticipation of results from this simple challenge. ;-)

Besides, its hard on your sides when you laugh....

snip

> a couple of box tops?
> 'Doc

Let me explain what provoked that comment. I came across
a stepper motor and a driver. Now I know they can be
controlled by a computor keyboard and I understand that
there are 'free ware' programs for them.
As a ham who likes messing with antennas I assumed that
there would be plenty of articles that discussed these
motors. What came to mind was benign things as operating
a tuner at the antenna using step motors,automatic antenna
tuners that recorded motor settings for frequency change,
a loop antenna controlled by a stepper motor according
to frequency use e.t.c.
I hunted thru 20 years worth of Q.S.T. since these things
are so basic to ham radio.I found very little, so
obviously what I think is of interest is not what the
readership wants. I must admit that I opened each
Q.S.T. at it's center and then flipped back to the front
thus I did not flip thru every page.
I am not computor literate so If anybody can point to such
an article that will allow me to make a automatic
remote tuner using purchased computor parts e.t.c.
that adjusts with frequency change I would be in
debt to them.
Is putting a tuner at the tower top an old wives tale?
Art

Thanks for the info. I figured it wouldn't make much of a difference,
but it doesn't hurt to check. What's funny is I posted this then just
remembered a buddy of mine had one up a few years back and I didn't
ask him. I sent him an e-mail later and he confirmed what I
suspected. Thanks again!

I would like to find the element positions on the boom of these antennas. I am working on some side mounting ideas for installing these on the side of some Rohn 45 and want to determine how much rotation I will have with a standard rotor off the side of the tower (not a ring rotor).

Any information would be appreciated.

Hmm, Interesting, Art. I was thinking of a stepper motor setup for my magloop. In my other hobby, amateur astronomy, we often use a stepper motor setup to point our scopes where we want them.

Seems like a not-too-difficult task to make an autotuner in similar fashion.

I share your surprise that this isn't more common.

Oh, man, you missed your chance. The way to have done that is to coat the bolts before pouring the cement, since metal inside cured cement is "protected" as the water is bound and little oxygen is present. Otherwise bare rebar wouldn't survive. In your case, the best approach is to remove a small amount of cement around the bolts, give the bolts a good coat of high quality paint as far down as possible, and backfill the surround with hydraulic mortar (doesn't shrink) or good epoxy. As much of the bolt as possible needs to have a good coat of enamel to keep the oxygen away from the surface. Then, go look at the way commercial self-supporting poles are mounted to their bases. They leave an air space under the plate by mounting the tower between nuts, rather than hard against the cement. This allows inspection and preventative maintenance, since nothing will be a permanent cure. On the other hand, if you can keep the area around the bolts dry with proper drainage, it will take a while for 1" bolts to rust through.

"W.G",
When you boil all of that down, all that it says is
that his program uses a secret algorithym (or is that
an 'Al Gore-ism) and that he thinks it works well. It
is an opinion, not a proven fact. (You know, about like
antenna manufacturor's gain claims...)
I very much doubt if ol'Frac cares one way or the other
about what I think or say, so I have a feeling that he will
not 'step up' to prove my opinion wrong. To do that he
would have to disclose what his secret 'Al Gore-ism' is,
and I don't plan to 'bate' my breath over that either...

I agree. Water doesn`t combine with iron to create rust. Oxygen combines with iron to create rust. Once all the free oxygen has combined, rusting stops unless additional oxygen appears.

I also have left an air space under the tower leg pads in a self supporting tower as George suggested, by putting the plate between nuts. In fact I`ve done that many times. But my purpose was to provide a final adjustment to remove any slight inclination from the vertical. In some cases, I grouted around the air space gap at the end of the job, but everything was galvanized. Air space would have been better.

Art, what kind of precision do you need for your tuner? The autotuner portion of my minibeam uses a remotely controlled L-network that puts some capacitors and coils at the antenna, and switches inductance and capacitance with relays in a binary sequence...in other words I have coils of .2, .4, .8 and 1.6 uH and caps of 50, 100, 200 and 400 pf. These can be switched in combination to give any combo of L from .2 to 3.0 in .2 uH steps, and C from 50 to 750 pf in 50 pf steps. The relays can be controlled much more quickly than a stepper, and don't need periodic calibration.

It is similar in some ways to the SGC and LDG autotuners, except that I remove all electronics from the antenna except the coils, caps and relays. I did this because of the problems I had with RF near microcontrollers, susceptibility of lightning damage and the inaccesibility of the electronics if damage does occur. The software can also do more when it's running on a powerful computer w/lots of memory as opposed to a PIC chip.

In the shack I have a controller which selects the relays, and interfaces a directional coupler through an A/D converter to input SWR. The interface communicates to the computer over RS-232, and my software does the rest.

This works fine for antenna matching of reasonable length antennas. I limit my tuner to L-network config because I am matching an element that is electrically short at all frequencies...and is limited to 14-30 MHz. For a wider matching range you would need a Pi-network, or the ability to move the shunt elements to either the input or output side.

For the reflector tuning in my minibeam I use a combo of relays and a stepper, because I need very fine tuning steps of .01 uH or so...which can't be done with switched coils.

When I finish my minibeam article it will have details of all this. I may also write a separate article on an expanded remote tuner that is more general in nature and not limited to use with an electricslly short antenna. If response to the articles is good, I will make kits available for folks who want to duplicate them without doing all the work.

Bob, I saw that and thought that I was home and dry.
But then there was no offer of a circuit board for sale
and if I remember correctly the software was not
made available . I suppose eventually I will have to seek
and pay somebody to do it for me. Thanks for jogging my
memory for me, I think that such a board would be an
excellent accompnyment for loop antennas users.
If there was a follow up re the controller board
and software or another method please let me know
Thanks again

Art,
Nothing at all 'wrong' with putting your tuner
on top of the tower rather than next to the radio.
I can't give you a reference to a specific article
but it shouldn't be too difficult to 'interface' a
stepper motor function to a computer. Not being an
engineer, or a computer programer, the degree of
difficulty may be a lot more than I would care to
tackle, but for those who are either of the above
(at least to some extent), it really shouldn't be
that much of a 'much'. It also won't be simple.
HeathKit at one time made sort of a 'tuner' for
antennas. Basically just a large, two section,
variable capacitor that was remotely controled. I
think it wasn't much of a success because it was not
small, or light weight. A tuner at the feed point of
an antenna isn't an old wive's tale, it's just that
in a lot of circumstances it isn't very practical.

With commercial ready to go units in the $200 range, it is hard to
rationalize trying to design/build one now days. LDG makes the RT-11
Autotuner that is waterproof (water resistant) and remote mountable
and sells through www.amcominc.com for $209.

Something else to consider is a gear-head motor. I can't
remember who it was, but before I left Intel in AZ, I sent
a few gear-head motors to a ham on the West Coast for the
purpose of a remote tuner. The devices run on plus or minus
12 vdc and will drive a variable capacitor and/or a rotary
inductor. I obtained the motors for $2 each from a surplus
place in Phoenix (7th Ave. and I10). Last time I checked,
they still had some.

There are a number of stepper controller boards available if you want to control a stepper through software. The least expensive I have tried is from Peter Norberg,
http://www.stepperboard.com/

His boards will control 2- unipolar or bipolar motors per board, depending on model, and have built in drivers for up to 1A per phase...start at about $40 and are available in kit or assembled. If you want TTL inputs or outputs to control relays, A/D converter inputs for analog, etc., you can buy more complex boards from a number of sources, but the price goes up considerably.

Most boards use simple ASCII commands, so you can test them with a terminal program, and most give sample control programs in C or VB with source code.

If you just want to run a motor forward/backward with switches...there is a controller chip available for about 5 bucks to do it...EDE1204. You would also need a driver chip like the L298, since the controller chip is TTL level output and thus limited in current. These are available from places like Jameco.

Larry, the three month article in Q.S.T provided the main essentials
as part of his homebrew tuner.
I would like to make various loop antennas for my self that would
cover all frequencies from 1.8 Mhz to 30 Mhz The controller for these
would recognise frequency reception and tune a capacitor
automatically. The capacitor would be the homebrew part which I
control with a stepper driver that emits EMI unfortunately.(Steppir
antennas do something like this but will not sell the controller
seperately)
Isoloop made a control for their loop the business has now been
abandoned.
This was not computor driven but had a chip in it that polled either
sound or SWR but only for 14 thru 30! It did use a stepper motor I
believe in the loop that did not generate EMI that generally plagues
steppers and ofcourse, without the need of a computor it was mobile
which is a much better aproach for many.
I would think that with the many loop antenna out there, homebrew or
other wise,such a controller will satisfy a need. I also believe that
what you are contemplating will satisfy a need also but for base
homebrew antennas,the difference being that that the capacitor would
move fairly fast and then backtrack slowly in SMALL steps, or for home
antennas preprogrammed positions.
Regards
Art

Art,

The Isoloop system was manual tuning, which you can do with the 2 chips I mentioned. To have a system that automatically tunes requires quite a bit more sophistication, like what I do with the reflector in my Autobeam. You have to monitor SWR and report it to the software, then control the motor to minimize SWR. The software can be on a computer or a PIC chip. You need a stepper controller and an A/D converter at a minimum.

If that's all you're doing, you can probably skip the computer and make an analog servo system. If a capacitor is all you are controlling, you could create a bridge circuit that would control a servo motor and balance itself by nulling SWR. A standard servo will give you 180 degree rotation with about 1 degree accuracy.

hi... mitch here in mobile...

i just took my ar-40 down which had been holding
my 6m beam for ?? years... i need to rebuild it...

mfj has the regular manual as a pdf file on their site...
but no schematic for the controller or the mechanics
and schematic of the rotator itself...

a google search does not turn up any source of the
schematics or mechanical drawings...

any suggestions??

thanks
mitch, w4oa

Hi, folks.

I am still looking for the KLM 15M6 and 10M6 monobander manuals. I know there are quite a few out there who are still using them so, please, guys, do me a favor...
If you don't have time to scan or copy them, let me know and I'll arrange a FedEx pickup for you to send me the originals so I can copy them, then I'll send you the originals back. Or something. Name your price.

I'll even settle for only a diagram with measurements.

Thanks and 73 .... Zoran WA7AA

snip

What a great feed back I got from you guys, thanks a bunch.
The screwdriver controller seems a good aproach (price and time wise)
as does the qst article form. I have lots of driver boards which are
made for computor input plus motors (and a stamp form)but have no
software.
My capacitor for the loop antenna is now set for the normal
half turn of use with the other half of revolution having
a door knob capacitor added to extend the range and also
to allow the use of a additional high value doorknob to use for
160 meters, this I control using a P B circuit plus commercial driver.
Also found out that the QST author does have
boards available plus components for sale but still complex to build
but alas no program.
Since most experts on this forum point to the simplest all round
antenna
being a long dipole and tuner it would appear that Larry would have a

great niche for his auto antenna tuner.
Thanks again for all inputs.

Source record: 132765

Has anyone ever tried transmitting the yellow and black plastic fence "wire" with the aluminum strands braided in? I have used it in receiving antennas and it has worked well. I am thinking of using it for a QRP portable dipole for 20. In my receiving antenna, I wrapped the coax copper around the poly "wire" 20-30 times after gooping it up with the stuff that electricians use (Nolox?) and sealed it in shrinktube. It has worked well and can be drawn TIGHT. The aluminum wire woven into the poly is pretty fine and has oxidized through in one instance where water running off the barn roof poured over it for a few years while it was being used for its intended purpose. It can be rolled up very easily and carries enough current to electrocute a rat!

1079. HyGain 402BA help needed

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-21 04:43:43 UTC
From: Bill Turini <hamshack@hamanuals.com>
Message-ID: <3DB385FF.3000604@hamanuals.com>
Source record: 132764

I was given a HyGain 402BA (40mtr 2 el beam) that had the boom broken, etc. I've got it all cleaned up and ready to re-assemble, but I'm not sure of the element length.

I have a copy of the original HyGain manual, the MFJ (402BAS) manual, and they both are different from the length of the elements when I received the antenna. 3 measurement. Which one do I go with?

Anyone have any comments, or a NEC file?

Thanks

Bill

Source record: 132763

Kirk,

This is a 2 el beam for 10. 15, and 20 meters. I seem to remember the boom length is 8 feet. I had the 4 el version (TB-4H/TB-1000) and it was a good antenna. The weakness was in the boom to mast fixture. Be careful not to tighten the bolts too tight or the fixture splits (I have the TB-4 fixture with a split still in my junk box).

Be sure to get the antenna as high as possible and it will bring in plenty of DX (try for at least 45 or 50 feet).

Source record: 132767

Hi all,

friend of mine is licensed now. He lives in a 9 floor high apartment building - he shack is in the first floor. There are some cable ducts, but this will end up in around 25m (75ft) vertical cable length.

Can a coax, like the RG-213, be mounted in such a length without damaging it due to the own weight - and stretching it.

Any comments are welcome

If he is afraid to hang the RG213 cable from the top, your friend can also strap the coax every meter to a strong rope.

the main problem isnt can RG213 hold up under that long of a run but can you get a signal out RG213 is pretty lossy at anything over 30mhz so if he is planning on running HF only he will be fine if he plans on running VHF or higher he would be better off getting a better grade of coax like 9913 or LMR400

I need to shoot some line over a couple of 90' trees to hang a loop antenna. This weekend I was in a surplus store and saw a 1000' spool of "Paraline" @ 6 cents per foot. I can't find out much about this product except for a reference to it on the net that refers to it as "Nylon Draw Cord". It is seven strands of string enclosed in a woven nylon sheath about 1/4" diameter. Does anyone have experience with this product? (or have any other recommendations?). Looking for low abrasion and high strength. Jim, W4VJ

I'd worry about the coax pulling right out of the coax connection. Might be a good idea to tie a piece of rope to it close to the connector, so the connector solder isn's supporting the whole weight.

Hi all,
thanks for the responses. Well, my question actually was: can the coax mechanicaly handle such a length if its hung free in a cable duct. There will be no chances to open the duct inbetween. The cabling will be done more or less 'under cover' from the roof (9th floor) to the 1st floor. My concern is the weight of the cable and if it will be damaged due to the own weight.

Remark: I installed my RG-214 cable in a 4 floor building. I was in the shack, another ham on the roof. He screamed - don' pull - I screamed into the hand-held - don't feed with force - Finally, the coax shot out of the 2 inch vertical cable duct with immense speed, like magic. It was no ones fault, as we finally realized - out of the own weight of the cable - it shot down the cable duct.

If its longer - will it stretch or even break ?

I have been using a similar cord for about three years now, since the local walmart quit carrying tarred nylon "trot line" in the fishing department. The cord I use is about 3/32 thick, similar to "sash cord", but with an olive green jacket.

I pulled down(last month) three wire antennas that had been up for between 1 and three years.

The cord on all three was somewhat less flexible than it had been when new, but seems just fine otherwise. The outer sheath is not showing any signs of rot(yet) but the lines don't get much exposure to the sun either, cause they are in dense cover. A single strand can still hold my weight (175 lbs, bouncing). It appears to have lost its stretch. I tested a piece of the oldest cord.

I plan on re-using the old cord when I put my antennas back up after leaf fall. The jacket is still smooth, and it slips over the branches easily enough. (I like the tarred nylon better, but I can't find it anymore, and it doesn't slip as well over tree branches.)

I bought this cord from Cabelas(gc-51-1527) for 35 bucks per 1000 foot spool. That works out to around 3.5 cents a foot. I ordered a couple of other things at the same time, so the shipping charges were mitigated. Its olive green color blends in really well, its hard to see up in the foliage.

But 6 cents a foot isn't too bad. I'd guess you can easily expect to get at least five years out of the cord. I usually have the branches break before the cord does anyway. It does tend to stretch if you are pulling a heavy coax.

(On my 50 foot support, I used two lines. I attached a stainless 2 inch o-ring, and used that line to pull up another line(passed through the o-ring). Then I pull the antenna/coax up using the second line--the o-ring is smoother than a tree branch, and doesn't snag like a pulley can with small line. Its also less weight being drawn(sawed?) across the branch. Keeping the two lines from snagging on one another is the drawback)

From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3DB4149A.619498FE@us.ibm.com>
Source record: 132774

Probably a stupid question, but I am a little slow:

I simetimes chase stations on 10 meter CW that are right at the noise level. This led me to wonder what is the "noise level" that I hear. Is it internal receiver noise or the "ether noise" or something else? (I am using a TenTec Omni 6+, and I have no reason to suspect it is not aligned and operating correctly. There is no unusual local noise that I know about.)

The reason for my wondering is this: I plan to replace my tower soon and will need another coax run. The total coax run (to my quad, which seems to be fairly well matched to the line) will be about 175 feet. I normally use RG-213. If I change to LMR-400 (or something similar) will this improve my received "almost noise level" signals on 10m? Or will it simply raise the total level of the signals+noise without improving the ratio of the signals?

Ten meters is around the range where receiver noise figure can come
into play. On the lower bands, atmospheric noise dominates over
internally generated noise. On 10, there can be times when the band
noise is low enough that a receiver designed for maximum overload
performance may have a noise figure high enough to degrade received
SNR. The better radios, and I would guess your Omni, have preamps
that can be inserted to improve the nf. Therefore, I doubt that the
receiver is the limiting case.

|this improve my received "almost noise level" signals on 10m? Or will
|it simply raise the total level of the signals+noise without improving
|the ratio of the signals?

The difference in matched attenuation between 175' of RG-213 and
LMR-400 is about 0.7 dB. This difference is "in the noise" (sorry, I
couldn't help myself <g>). If the match is less good, then the lower
loss line might offer some system improvement, but more on the
transmit side.

A simple (but not conclusive) test would be to point your antenna in
the direction of lowest band noise and then switch to a good
termination (dummy load) and see what happens to the receiver noise. A
reduction in noise on the dummy load indicates that external noise is
still the limit.

No change indicates that either the nf could stand improvement or that
you are operating on the downside of the sunspot cycle, where a 0 dB

nf isn't going to help.

Bill,

Noise level could either refer to noise picked up by the antenna, or receiver generated noise as defined by its noise figure. Unless you live in the boonies, the latter is of no consequence below 144 MHz; probably never at 10 meters.

RG213 is fairly ancient, and rerlatively high loss at 28 MHz. With 175 feet of feedline, and 100W rig, you would get something like 60W into the antenna. On receive, both signal and noise will be attenuated by the same amount. LMR400 has a loss of slightly more than 1/2 that of RG213. In fact, the skinny LMR240 is only very slightly worse than the 213.

LMR400 is too stiff to run around the rotator; so, you would need a short piece of more flexible cable to extend below the rotator. Newer versions of Belden 9913 are just about as good as the LMR400, and may be cheaper. Do not use the original 9913 outside. If water gets in one end, it will come out the other. A friend of mine found that out the hard way when he discovered a large puddle of water under his rig.

BTW, if you use cheap 259 connectors with low loss coax, you may have to remove some strands of the center conductor to get it ti fit the connector pin. Better to buy the right connector.

You can find all the cable specs, and prices at www.cablexperts.com .

Wolfgang,

You might want to check the weight of RG213 relative to more modern cables.
Seems to me the lighter cable would put less strain on itself.

Have heard from users that the MFJ is a lightweight mast -- be careful of
the load.

For a heavy weight by DK9SQ -- tested here in San Diego see URL:
http://www.bright.net/~kanga/kanga/dk9sq.htm
Used here for verticals, inverted vees, dipoles during Field Day. A winner

For masts of this type -- there maybe some carbon content -- so keep wires
away from the mast by a few inches when making verticals.

They are 24vdc gear head motors made by Barber-Colman and they
work well at 12vdc with reduced torque. Last time I was in Phoenix
they were still sitting there priced at $2 each.

Thank you both for the comments. As I understand it, better coax will probably not help the "noise level" signals on 10 meters. It would get more power to the antenna, but this is not such a significant concern for me. "If I can hear them, I can usually work them." (If not, I turn on the linear.)

The RG-213 is attractive because it is so durable and forgiving of flexing, bending, water, etc. Nevertheless, I may go for the LM400 for the largest part of the cable run. I hesitate to put more junctions in the line; there are already too many with a coax switch (at the antenna), lightning protection unit, and another coax switch at the rig. Also, I *hate* installing PL259 connectors --- I just am not very good at getting a nice, even connection to the braid.

If you have to "mix" dissimilar metals, use stainless steel
between them. For example, I use a brass screw soldered into
the center pin on the S0-238 for my gamma match. The screw
passes thru a hole in the flattened end of aluminum tube.
I drill an oversize hole, and use stainless washers with either
brass or stainless nuts on each side of the hole, to hold the
aluminum tube to the brass screw. The aluminum is "sandwiched"
between the stainless washers.

If you mix aluminum and brass directly, the aluminum begins
to turn into a white powder and eventually fails.

There is a simple test you can do.

Tune your receiver to your favorite frequency on 10 M. Note the noise level. Unplug the coax, or switch to a dummy load.

If the noise level drops, most of the noise is coming from outside your receiver. If it stays the same or drops just a little then your receiver is contributing most of it.

In general, most modern receivers/transceivers are quieter than they need to be, as the external (atmospheric) noise is much stronger on the HF bands than the receiver noise. Ten meters is an interesting band, however, as there can be times when it is very quiet.

I would think that RG213 would be fine on 10 meters, but if you can afford it get the lower loss coax. It certainly won't hurt.

Regarding the mast I can highly recommend it. I used it on several
occasions while on holiday (EA6 and EA8). Used a Doublet antenna with
the mast. It is very stable although very light weight.

Larry,

Now this is contrary to all theory, but this is what my experience is:

Had a full 1/4 wave 40 meter vertical hanging from a 60 foot tree branch, 4 radials, feedpoint about 20 ft. Also a conventional 40m inverted V at the same height.

Made comparisons with a group of people in western NY, about 300 miles, and group in Wisconsin - about 1000 miles away. People with verticals thought my vertical was better, people who were horizontally polarized thought the inverted V was better. This was about 10 years ago, but I don't recall any dramatic difference in received signal strength between the two.

Hi Bill:

I would suggest that you look at Davis RF "bury-flex". It's a LM-400 clone that has the advantage of a stranded center conductor. Also it costs less.
As for the PL-259 problem:
What I do, is I remove the jacket, then I tin the braid for about a 1/2". Then I use a small tubing cutter cut the braid. The small tubing cutter is designed to be used in tight places and is very small. They can be found at any hardware or home center. The distance from the edge of the tool to the cutting wheel is just the right distance to trim the braid. Next I strip the center insulator back to the edge of the braid. Then screw the PL-259 body on and solder the braid through the holes. It's much easier when the braid is tined.
Also DON'T use the cheap PL-259 that are all over. Mostly I think hams buy them because they have Teflon insulation and a "gold" center pin. None of that means anything because all that I have measured are the wrong size. If you measure them in the area where the braid is soldered, I find most of them 0'05" bigger in diameter than the old standard amphonal PL-259. That means you have an extra 0.025" all the way around the braid to fill with solder. So I buy only the standard amphonal connectors and I have no problems with soldering them on.

Sounds like standard parachute cord. Is rated at 450 pounds tensile strength
but is actually quite a bit stronger. Like any nylon, UV eats it but the
cover protects the strands. It should be good for several years if not
overstressed. The most weather resistant rope is polyester.

HI

The big problem with these fishing poles is that the sections pull out
to fit. This is ok if you only intend to use them occasionally.
The poles tend to wear very quickly at the taper joint especially when
used in damp conditions. This results in the ends splitting as you need
to pull each section tighter and tighter into the next one.

Much better is what is called a put over pole, which you erect by
putting each section over the top of each other.

Most of my limited activity is portable and I use a couple of these type
of poles which are of the old heavier Fiberglas style. They are about 12
yrs old and they gave me good service when I was able to fish.

Both poles are 10 mars long but with the aid of a few old beachcasting
rods and other bits of various poles lying about I am able to extend
these to either 12 or 14 meters.

If you go for the fishing pole version you can purchase spare top
sections as they are easily broken.
To stiffen the tip section I have replace it with the top section of a
beechcasting rod on one pole and the other pole uses an old kiddies
solid glass spinning rod.

Only prob I have found with the put over style pole is that it can be a
bit awkward to lift upright in a stiff wind.
Rest of the time it takes me about 15 mins to put the pole together
along with the feeder stand-offs and antenna wire, then just lever it up
over the arm of the wheelchair and attach it to the brackets on the motor.

My experience was disappointing. The noise level on the vertical was two
S-units higher than a dipole and the signal levels averaged two S-units
lower on the vertical compared to the dipole. At my location, the vertical
wasn't worth erecting or even leaving erected.

Hi Larry,

Look up the tri-band vertical design by W6SAI which can be found in several antenna books. Three vertical wire radials, four radials per band, made from rotator cable cut to quarter wavelength. Support it with PVC pipe, hang it from a tree. Don't know about 40m, but 10/15/20m version worked very well.

Good Luck,

Bill, W4WNT

1118. Wellbrook : what a service !

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-22 01:42:29 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210211742.35640912@posting.google.com>
Source record: 132806

Hi,

Go for some publicity...

Some days ago I experiment a failure of my active magnetic loop from wellbrook (http://www.wellbrook.uk.com) that I cannot solve without spare parts.

NB. The quality of the antenna or parts is not involved in this problem.

I contacted wellbrook by email that immediately suggested me to make some measurements and various tests. Good news.

After have received my figures and read my appreciation of the problem in the next day Wellbrook told me to send them back the antenna interface, what I did immediately.

2 or 3 days later (time to go from LX to UK) they answered me that the interface was OK and they were sending me a new antenna (complete set at no charge as the warranty was still running).

In the meantime, as I already reviewed and tested the receive antenna ALA-330 (see my website) I suggestdc them to replace this model with the emitting one, the ALA1530.

No problem they only ask me to send them back the new antenna just sent and to pay some ï¿½25 extra.
Fine. I quickly intercepted the deliver company in LX and they send the loop back to Wellbrook.

A few days later I received the new ALA1530. In fact the $25 I paid as a complement did not only cover the price difference with the ALA330 but took also in account (and largely) my charges when I had to send them the interface back.

So I would like to congratulate here this company for the quality of his customer service and his quick reaction. This behavior becomes rather rare when we read post of forums and I think it could be mentionned.

Hi,

As usually, all depend of :
- what is your budget...
- what HF bands your want to listen to/work with
- if you need a ground plane, couterpoises or surely not
- what is your maximum height, weight, etc

Titan GAP has probably a better reputation that MFJ, but this is a
personal opinion.
There are also many excellent models to Cushcraft (R6, R7 or similar),
Butternut, High-gain and few other manufacturers.

As suggested check first the technical reviews on eham.net (where I
also actively participate). That could help you to select a few "good
verticals" and from there to get a closer look.

NB. Personaly I appreciate first the Cushcraft then the Butternut
vert. Note also that you sometimes find their user or assembly manual
online.

I used one for a few years and it was excellent. Of course I had 60+
radials and was on a cliff overlooking the sea and had a VP2E callsign
to light it up with.
JA pileups generally ran 20 over 9 in the mornings and I often had to
work 'em by call areas.
A sloppy dipole at the same QTH would barely hear the JAs.

I have used DeLorme's 3-D TopoQuads (one bunch of disks per State) to make profiles. The process is quite simple. Do not forget to use a 4/3 radius when estimating where the radio horizon is located (to account approximately for diffraction).

I also use Topo USA (DeLorme) v3, which does not have quite the resolution of TopoQuads. I have not tried to make profiles with Topo USA, but I expect that it could be done.

1122. Mechanical resistance of a G5RV ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-22 02:31:50 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0210211831.6f57b012@posting.google.com>
Source record: 132810

Hi,

I have to install a new G5RV in my garden, tied between the chemny, located at about 8m high, and a remote mast, 30m away. The QTH is in an open field and supports from time to time gusty wind near 80-100 km/h or faster.

I need your comments about practical considerations dealing with its attachment and mechanical resistance.

- what force or tension supports the metallic wire of a G5RV (bought from universal-radio, $27 + charge). Much more than 100 kg ?

- Must I tie it until it is really straight between my chemny and the mast or must I accept it curves a bit (50cm-1m in the middle) to resist easier to gusty winds ?

- what must be the diameter of the metallic remote mast to support the tension of such wire antenna. Is a 2" aluminimum tube 8m high enough (or too large, or do I need stanless steel) if it is attached on its last 50 cm or 1m on the side of a cottage with 4 U-bolts ?
NB. the cottage where the mast will be fix onto supports better the gusty wind as it is partly protected by nearby high pinetrees.

- at last a stupid question maybe, what kind of "knot" do I use to fix the wire antenna at its ends for a permanent installation, the same as for my shoes, but doubled or tripled or a stronger one (I do not know marine knots but I can find them on Internet if relevant).

Thanks

Thierry

21 October, 2002

I wish all the concern was sincere, but clearly some is not.

Nonetheless, I seem to recall mention "mid/late October". The cluster is running straight out, 24/7, with in-house projects at the moment. I am also as busy as I have been in many years. I anticipate there will be a short lull within the next two weeks, and that is when I will run through this simple challenge.

At this time, I would like to give Steve Best the collegial opportunity to get one final chance to review his posited optimization figure of merit (FOM). I actively encourage him to scrutinize the FOM, and consult and confer with others to make sure--based on his VERY BEST SCIENTIFIC know-how-- that said FOM is not ill-posed or pathologically degenerate. After this opportunity, I will be forced to use his FOM in final form without any input from those who will run the challenge whatsoever. As a scientist, I will then have to make objective interpretations of the results based upon the I/O. Emphasis on 'I' . It is my personal desire to have these fairly presented and to give Steve Best a fair shot.

One last time: Steve, are you satisfied with the FOM? I will wait for your final presentation of it before commencing the challenge. Take your time; no rush from this end.

73,
Chip N1IR

Wolfgang:

RG-213 or 214 can easily support the weight of 100' (33 meters) of itself, but the upper attachment requires the correct hardware. There are two methods, the hoisting grip, which is like the braided finger trapper, but made to grip and support cable. See a commercial electrical supply dealer. The second method is to form the cable around a fixed pulley which is slightly larger than the minimum bend radius, fastening the cable back to itself with some form of permanent strap. Tape would be marginal, but might work if enough of it is applied. I have 100' of RG 214 supported with a hoisting grip inside the mast of my LPA, and expect no problems.
Good luck.

Do NOT use an aluminum wiring device to attach anything to a copper or copper alloy metal like brass. Stores like Home Depot and any electrical supply house carry copper compression connectors in many sizes which are called "bugs". Use one of those.

>

Not necessary if all the parts are copper or copper-based.

AMEN!

Chip the concrete away from the j-bolts a couple inches into the
concrete. Power wire brush off all visible rust. Apply mil-spec yellow
zinc chromate primer to the bolts. Then apply several coats of
Rustoleum enamel. Let it dry for a week in moderate temps (>65F). Wrap
the bolts tightly with 3M #88 tape so that the tape extends an inch or
two above the surface of the concrete. Backfill the holes with a good
industial-grade non-shrinking or controlled expansion grout with a bit
of a water-shedding slope around each bolt. Coat all of it with hot
tar. Sandwhich the hot-dipped galvanized adapter plate between Grade 8
heavy-section galvanized nuts.

Prayer won't hurt.

1130. Old Hustler Mobile Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-22 07:10:02 UTC
From: Martin Hibbs <mhibbs@ipeg.com>
Message-ID: <3DB4F9C8.3039AD3D@ipeg.com>
Source record: 132818

Does anyone out there recall or know about an antenna by Hustler/New-Tronics which went by the nomenclature of "RB-20"? I have come across one missing what I believe to be the uppermost portion of the radiating element. FYI it is a mobile antenna and has an NMO style base connector with a more or less typical base loading coil (looks about like a 5/8 wave CB coil) and a multi-piece screw-together radiating element which fits into a larger than usual typical Hustler adjusting mechanism. 20 meters? Or....???

Any manuals, diagrams, fond memories, dimensions of the top element, verbal descriptions? Any information would be appreciated.

(And yes, I have done the web searching.)

Anyone?

Marty...

> LArryC, N3CCW, CN85

Worked great here for long haul stuff at night. But I had mine at 36 ft at the base. I used 4 radials, which roughly would equal about 50-60 radials if ground mounted. Yours should work fairly well, but be aware that you would need more radials to equal the performance I had. I note Cecil didn't like his, but he also didn't really use the proper number of radials for the low height he had his at. Or at least to equal the performance I had... I think he had his at 15-20 ft or so. About 1/8 wave up. I've already mentioned this in the past. 36 ft is 1/4 wave up on 40m. 10 ft is less than 1/8 wave. That means you will need MANY more radials to equal the four I used at 36 ft. You will need nearly as many as for a ground mount. Also, a ground plane or decent ground mount vertical doesn't even begin to show it's stuff until you start to work fairly long paths. I don't think Cecil ever tried any real dx with his. So that further skews his results. You have to get over 800-1000 miles on 40m, just to get to the crossover point where the vertical starts to equal or outdo a dipole at 35-40 ft. When I had my GP at 36 ft, and a dipole at 36 ft, 800-1000 miles was about the norm for the crossover point. At 1500 miles, the GP never lost. Not even once. From here to VK land or any other dx, the GP was waaaaaayyyyy better than the dipole. But if I worked from here to say Ohio, they would be about even on average. I think you would almost be better off with a ground mount if you can't go any higher than 10 ft. At 10 ft, the proper number of radials for decent performance will surely not look too hot, and may get in the way. They could also be a shock hazard if they could be touched. It would be neater to lay them all on the ground being you need so many either way. Lets say you need 60 to equal the performance I had with 4 at 1/4 up. At 10 ft up, you would likely need at least 40 or so. If you want to run elevated, I'd get at least 25 ft up, with 36 ft being better. 36 ft is easily done using a radio shack pushup mast. You HAVE to get that high up if you want good performance with only four radials. Ask almost anyone, including Cecil, who ran one fairly low, with only 4 or so radials, and they will tell you they didn't like it. I believe them, as I wouldn't like it either compared to the one I ran at 36 ft. I had a ground mount with 32 radials, and it was no match to the GP at 36 ft. Like day and night. A vertical is a great dx antenna on the low bands, but you have to use the proper number of radials if you want 1st class results. Sure, just a few will work at low heights, but

mediocre at best. If you use 120 radials on a ground mount as a benchmark, at 1/8 wave you will need 50-60. At 1/4 wave about 8-10. At 1/2 wave, 3-4. All are appx equal antennas as far as ground losses. But the patterns will vary from the effects of ground. 1/4 wave up, is a nice height for 40m dx, with very little high angle lobes. Note my 4 radials were not "optimum" compared to 120 radials. But it still worked very well, about equal to 60 when used on the ground. Would have been even better if I had doubled the radials to 8. The only people that ever beat me to VK land, were using arrays of some kind. Either yagi's, or bobtail curtains and such. No vertical loop or dipole ever beat me when using the GP. Period. Most of the people with vertical loops couldn't get them high enough off the ground to compete. I had locals with bobtail curtains that beat me nearly every time though. "amounts to an array of 3 verticals". The difference between my dipole, and the GP was usually 4 S units on most peoples S meters in VK land. Of course, an S unit can amount to anything, but that was the usual report I got from all concerned over there. From here to the west coast of the US, "1500 miles", 2 s units difference was the usual report I got when comparing. The difference would have been smaller if I had the dipole at 65 ft, "1/2 wave up", but I can't get mine that high.

Just curious, Mark, if you can get your vertical to 65 ft., why can't
you get your dipole to 65 ft.?

How can I tell if the tint on my car windows is metalic?

I have a 2000 Ford Taurus Wagon, and the side window where I would like to mount the antenna has a dark opaque tint around the edges with a transparent tint in the center section. If I mount my antenna on the transparent part it would be too low, particularly on 440 MHz.

Has anyone out there used a glass mount antenna on a Ford Taurus wagon?

Hello Thierry,

since the G5RV is a simple wire antenna, it shouldn't be too much trouble putting it up.

First, the G5RV has a 10 - 11 m length of balanced line that has to be installed vertically. Your chimney, needs another 2 - 3 m ! anyway... try to avoid metallic objects by staying away 30 - 40 cm for the balanced line.

Second it can be installed as an inverted V dipole, with ends attached lower, say 4-5 m high. (mine is like that) Think about putting it up higher in the middle on your chimney (if your chimney is in the middle).

The force needed to pull the wire is about 5-10 kg on each ends. You dont need to play the cello on the string! ha ha.

Try twisting the balanced line a bit on the way down, it will reduce the wind grip on it. (maybe 1 full turn per meter)

For knots, I personnaly like clevise knots (3 or 4) (cl&#65533; simple ou double) or a bowline (noeud de chaise) , as they are quite easy to untie, but they stay tied when you want them to. (scouts 101)

I just passed my General exam (woo hoo!), and my TS-430 is coming tomorrow or Thursday. I live in an apartment, and I have balcony access. I was a Tech Plus, so I have been running a 10 meter vertical out there without any problems. Any ideas on which bands I should try to use? I mostly will operate after 5:00 PT, and I am in Washington. What bands would be open after 5:00? Will 20 still be open? I really don't know, beause I don't have a good radio to monitor the bands yet.

Also, anyone have some great limited-space antenna ideas for me? I have a balcony (with wooden railings) to work with.

Also, what are some of the favorite HF bands that people use in this newsgroup, and why?

Thanks,

Scott Keller

I recently moved to my new home with antenna restrictions; hoever, I have been authorized to install a wire antenna. I hav a 40 foot tree on my postal stamp size lot, so I would like to install a delta loop. I read the article in QST (May 2000) about a stealthy delta (p.47-48. I have a couple question that I hope someone can answer my questions before I decide.

1. Does the triangle have to be equilateral (all size of equal lenght? I planning a delta loop with 30' x 30' x 50'. The base of the antenna will be 50' and will be conntected to a SGC-237 antenna coupler.

2. How does this antenna perform? I don't have EZNEC to model the antenna. I plan to work 10-80 meters. The antenna will be installed at 35' and support by my fence in my backyard. Note, the tree is about ten feet from the fence, so the two legs be pulled to the fence thus the legs will not be in the sam palne as the apex of the loop.

3. Is the antenna known to cause RFI? I plan to use RG-8 coax (80 feet) from the bottom of the antenna coupler to the rig.

Thanks for any input.

Mike

Source record: 132682

The sides don't have to be equal, but shouldn't be wildly different.

Performance depends on where you feed it and what distance you are trying to communicate. For close-in contacts, feeding the bottom center will be OK...for DX, feed at one of the lower corners. If you use a SG237, make sure that you have a good ground and/or counterpoise. The 237 won't work right in a balanced feed system unless the ground side is clearly defined, because the 237 is unbalanced by design. This can be done with a dipole by making the ground leg 5% longer than the other. With corner feed, if you just connect the ground leg of the 237 to the lower wire, you'll probably be allright.

Hope that helps.

If you compare a delta loop to a square loop, one of the sides is wildly
different. :-) The rule-of-thumb is that the more area in the center, the
better.

Hi Fred,

This is the middle of a contest over who can design the most optimum
antenna within the constraints offered (see quote below). In the
past, I have likened it to the story of John Henry who stood in
opposition to the automatic rail driving machine (Steve's effort to
design against a computer program). You are entitled to be puzzled
over the issue, but not with as much puzzlement as the original author
who has a convenient memory to forget Steve's longstanding answer:

As I have noted elsewhere, it is a fool's agenda to think this would have ever taken place - anytime.

You may also note that there is sufficient complexity to cloud the actual results - save one test that I have already mentioned. But again, fractals after having lost so overwhelmingly in the last contest, this undisclosed "optimization" will remain just so much marketing hype. Pay particular attention to the usage of "protected by pending patents" for that queer spin. If this goes into further discussion, you will undoubtedly be regaled with five reasons why it won't happen for every reason why it should (which begs the question, why was this challenge taken up only to then hide from it? The five-to-one ratio will probably be operative there too.).

Actually, the correspondence above is the second of two responses to "optimization" that have been abandoned in the field to the tacit admission of defeat. That, in the end, is a longstanding characteristic of fractals/cfa/eh and optimization - utter frauds incapable of close examination and worse (or better, depending on your point of view), withered in the face of competition.

Perhaps you've heard of the old joke of the guy on the street corner selling bottles of Universal Solvent. This optimization is like that seller offering a product on its merit, and conveniently neglecting to discuss the basic conflict in that specification. Universal Solvent in a bottle? Doesn't the solvent have the capacity to dissolve the bottle? No? Then what makes it a "universal" solvent? ;-)

If you follow the (cfa/eh/fractal) story long enough, the embarrassing humor of brash denial just pours freely - our cup runneth over....

Hi Thierry,

This has serious implications if you try to be straight as a ruler.

The strain on a hanging wire increases exponentially as the sag (curve) is straightened out. If you do your job very well, it might just collapse your chimney in the next gentle breeze! Chimneys are not designed to take a lateral stress (like that from a long wire suspended with a tight pull) only compression.

Take an example of a wire antenna weighing all of 1 pound. If it were 100 feet long with a 1 foot sag in the middle; then the tension in that wire is the weight multiplied by 48.9 (about 50 pounds NOT 1 pound). If a gust or two pressed the wire with 5 pounds of force, that too gets multiplied such that the chimney will experience a jerking, pulling force of 300 pounds. Those gusts have the same destructive potential against a chimney as 20 or 30 sledgehammers. If you are really lucky, the wire will break before the chimney.

No big deal if it curves in the middle. It will still work fine.
>
>- what must be the diameter of the metallic remote mast to support the

Depends on what the u-bolts are attached to.

Consider placing a guy wire on the tube, directly opposite to where you attach the antenna, to keep the tube from keeling over. Or get a stronger tube. Just depends on how much flex it has.

>NB. the cottage where the mast will be fix onto supports better the
>gusty wind as it is partly protected by nearby high pinetrees.

Pull the wire tip through the insulator, and wrap it a few times around the straight part of the wire. That'll hold, no problem. No fancy knots needed.

The rope that holds the insulator could take a sailer's knot, or any secure double- or triple-knot.

Mike,

I think you can get away with quite alot. I have an approximation to a 75 meter square loop, which is actually a trapazoid. The bottom horizontal wire is about 30 feet longer than the top wire, because I tried to get the bottom wire as far off the ground as possible. The sides are sloping. I am feeding one corner (at about 20 feet) through a 1/4 wave section of RG11. The shield of the coax connects to the bottom horizontal wire. I started with the dimensions as if the unit was square, and did not have to trim a whole lot. Resonant SWR afer the RG11 is about 1.2:1. The antenna works quite well. When I run the 1200W linear, people in Europe have told me I was one of the few loud stations they were hearing from the states.

<fmarshall@acm.org> wrote:

>There must be references, web pages or.......?

Hi Fred,

In response to this one particular question, yes they are available in
abundance:

http://www.qsl.net/kb7qhc/antenna/fractal/index.htm

This link leads to more than 300 pages of models, testing, and reports
of fractals alone. This is easily 50 times the coverage found
anywhere (everywhere) else (combined). Beware of commercial sites
that present the standard marketing hyperbole and beg off the
difficult questions to hide behind a shroud of secrecy, sham
testimonials, and the ever obtuse statement about being protected by
pending patents.

My pages represent a body of work first published on the net back in
early 1995 (it took other workers in this field some five years to do
far less). In the seven+ years that have followed, not one iota of
detail has been challenged. Some of it constitutes prior art that has
been obviously disregarded when it came to disclosure to the patent
office following their publication. You may well find (in the
archives) some discussion of legal actions being threatened - except
that such activity would come uncomfortably close to collapsing a
house of cards if actually pursued. ;-)

It is with this last queer attitude of scientific invention through
court suits that so lightens our day here in the group. You can
choose to ignore that soap opera, but you will then discover there is
very little real knowledge within the correspondence. In that regard,
my pages will provide a bounty of data and very little
editorialization (confined largely to one or two amateur design pages
that can only be best described as "ground warmers," see for one
particular example:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
where performance at -5dBi is characterized by the amateur inventor as
superlative....).

I've been mostly lurking for the last few weeks. My hope was that there'd be some really interesting discussion about antennas here. My impression so far is disappointing because there is so much flaming / impolite messages, off topic stuff etc.

Are there no standards of discourse in rec.radio.amateur.antenna ??

Or, does one simply filter out certain senders? That would be a shame to contemplate.

There are certainly examples of newsgroups where folks do stick to the purpose and avoid too much flaming. Can that happen here?

Buy? Why buy an antenna that costs $20 to build? Details are on
my web page. Exact dimensions are not important. Virtually
any antenna around those dimensions can be tuned to resonance on
all HF bands by varying the length of the ladder-line. The Wireman,
(800)727-9473, sells the 450 ohm ladder-line as do a lot of other
companies. I personally like The Wireman's #554, #14 stranded.

> Did you just solder the feedline to antenna??

Yep, with black tie-wrap strain relief.

> Does feedline laying on a roof cause a problem?

Depends on the roof and how wet it is. Laying on a roof causes
dielectric losses especially in wet weather. I know a ham who
glued plastic pop bottles to his roof and used them for stand-
off insulators.

> I want to switch to coax as I enter the house. Does this
> cause a problem??

Not if the ladder-line is the correct length and you have a
functional 1:1 balun/choke at the balanced/unbalanced junction.

Sounds like standard parachute cord, IIRC the max safe load is 500lbs,
but I could be wrong on that. Something close to that though. I use it
all over the place for small line tasks that won't have to be in UV all
the time.

Chip,

To be quite honest, I really don't care about the FOM, the antenna optimization or the challenge.

As I initially stated, I would prefer not to use an FOM. I would be satisfied if your computer GO came up a design, within the specified physical constraints, that had maximum radiation resistance and maximum bandwidth. I'm curious to see your computer's solution, especially how many GO attempts it took to arrive at the solution. Then, we'll compare your computer's design to some simple or arbitrary geometry that I come up with and see if it is significantly different.

> you get your dipole to 65 ft.?

The vertical was at 36 ft at the base. About the same as the dipole. I
just mentioned that as some would likely mention that a higher dipole
would fair better against the vertical. And it's true. But I still
think the vertical would win to far dx even if the dipole was at 65 ft
regardless of what theory or modeling might say. I know this was
pretty much the case with W8JI and his dipoles and verticals on 160m.
He had a dipole at 1/2 wave or more on 160m, "I think 300+ feet??"
and he said his ground mount verticals still usually were the best to
dx. I think the polarization itself has a lot to do with it. I bet if
you modeled the two in his case, the dipole would win on paper. But it
didn't in the real world. I wish I had a 65 ft support. My present
dipoles are only about 42 ft up. My short tower is only about 31 ft
tall counting the mast. But I haven't used that here at the house yet.
It collects dust in the garage along with my triband beam. Need a
rotor... MK

I'm going to convert my 80 m dipole (123' total length) to what
you have. I'm assuming since its close to 130 it will make no
difference.
Will the 80 m dipole resonate at about the same point whether
I feed it with 50 ohm coax or 450 ohm?

Don't I need a 9:1 balun to bring the 450 ohms down to 50 ohms?
450/50=9

After the 1:1 Balun is 50 ohm coax which you just screw into
a 50 ohm jack on the tuner right???

Is the 50 ohm coax length critical??

I think only real old, or radios in bad alignment would normally have a problem with sensitivity on 10m. I know years ago I made a preamp to go with my old drake R4, and the main purpose was to improve 10m. It didn't pan out. The drake was already good enough as is. The preamp just pumped up the S meter and trashed the radio out overall. The s/n ratio did not improve. So, being that radio was all tubes and made in 1965, I would think any modern radio should be plenty good enough on 10m. My newest radio "ic-706g" is very sensitive on 10m. ".16mv for 10db s/n" It has a built in preamp, but you don't need it. I almost never use it. I don't even use it on 6m or 2m.
>

213 is fine normally, but 175 ft is starting to get a bit long for 10m use. But even if you lose half your power, it's only about a 1/2 S unit in theory. I don't think improving the coax will help his s/n ratio much at all. He needs a bigger beam with more gain, or better band cdx. :)

1. No
2. Pretty well. I use a sorta delta on 80-10m successfully.
Need the tuner tho. I have worked the USA on 40m
and Europe on 20m and 15m fine.

3. I have not had a problem running 100w and often times 400w

My delta is straight up and straight out with the far side
sloping. I feed at the square corner and on higher bands
it radiates best from the sloper side.

The resonance of the antenna is not function of the length of the transmission line, excepted if the transmission line is unbalanced and feed a balanced load. In this case the length of the outer shield is to be taken into account. It's then better to place a lot of ferrite toroids at the antenna end to prevent the outer shield of the coax to radiate (see Maxwell in the chapter on baluns in his book "Reflections ...").

If your transmitter has no antenna tuner, it's better to adapt the impedance with a balun 9:1 in case you will use a 450 ohms line.

Source record: 132714

I have a question.

Can someone explain me (from the theoretical point of view) how 4 radials at a 1/4 wave height can replace 120 radials at the ground level. In my mind I have always thought that the radials are there to produce a mirror to the radiating 1/4 wave element. If you elevate the all system why is it less true? Because after all, the radials collect the RF currents and close the path.

Mike,

Since it sounds like you want a "one size fits all" delta loop, I am not sure that the following discourse will be helpful to you. I have tried several random length (non-resonant) loops and been disappointed - dipoles did a better job. However, I have found that resonant loops work great, so perhaps you could manage to cut this thing (these things?) to a resonant frequency and get better performance? If you can, here's some of my delta loop experience:

I am using two full-wave delta loops here - one horizontally polarized (40 meters, 143 total feet) and one vertical (30 meters, 103 total feet). They are both equilateral triangles (all sides of equal length), and I used the formula 1005 / frequ(MHz) for the initial length - although in practice I have found the correct divisor to be closer to 1030 for the desired resonant frequency. Since the natural impedence of a delta loop is around 100 ohms, I feed each loop with a random length of RG/8 + 1/4 wavelength of RG/6 to accomplish low SWR. The usable bandwidth of both antennas (SWR less than 2:1) is much broader than either band, so no tuner is necessary when used on their design band. The 40 meter mostly-horizontal loop is fed at an upper corner (my tower supports this corner), and I find the radiating pattern to be _very_ directional - away from the fed point toward the opposite side. The 30 meter vertical loop is also supported by the tower, exhibits no noticeable direction pattern [although EZNEC says there should be a slight preference in the direction of the elbow] and is fed 1/4 wavelength down from the apex to provide vertical polarity.

I like to work DX here, and due to previous bad experience with tuners and a G5RV (managed to get my WANTV - worked all neighbors' TVs - award in one weekend!) I shy away from non-resonant antennas. Due to your circumstances, you do not have that option. BUT - you might be able to optimize the antenna for a particular band by cutting it to resonance on your favorite band and then using the tuner for operation on other bands. I found that delta loop performance sufffers as the shape varies from a perfect triangle, so would suggest that you design for "equilateral" rather "as long as possible, even if it means that one leg is 20 feet longer than the others".

SOooo, if I have managed to sell you on the "equilateral, resonant on one favorite band and tuned on the others" idea... with the lengths you're considering, it sounds like you have room for a full wave loop on 30 meters (are you a CW kinda' guy?) or a wave-length-multiple on 10 - 20.

Steve,

The days of inspired empiricism are over for this field, and we all need to accept that the 'black art' has--not will--succumbed to something at least more inductive, if not deductive. At the very least, this is a design GUIDE if not a design DETERMINER.

If you can arrive at an 'optimized' design by a slap of solder here, a curve of wire there.. then the laws of physics can be invoked to replicate or exceed through simulation.

The issue of whether your care PERSONALLY has nothing to do with the requirements of SCIENCE.

I am a scientist, and I expect you to honor the fact that a colleague's time is valuable, rather than implying:, 'oh, yeh, I don't know,well... try this and go away'.

I await your thoughtful and final suggestion on the FOM.

Cordially,

Chip N1IR

Invoke the same methodology to the sim as the person.

Why, pray, is that apparently so difficult for you and Steve to see?

Also, Steve already agreed and provided an FOM. I am ,collegially, jogging him to be thoughtful in that choice and will magnanimously accept a modification from him.In fact, I openly offered to have him consult all those colleagues he talks to about fractal antennas--at least some of which I know are familiar with computer sims in antennas.

This is a credibility issue Rick. I am of the opinion that Steve possesses the knowledge and credibility to do this right, as any scientist should.

Enough said. I am off to fab antennas early. I look forward to Steve's final FOM at his convenience. As I said, no rush.

73,
Chip N1IR

Source record: 132622

Suppose one ampere of current flows from the center conductor of your coax into the base of a vertical antenna. Then one ampere must flow back into the shield connection, which is connected to the radials. If the antenna is very far from ground, there would be no loss except the small and insignificant (assuming the antenna isn't too short) conductor loss -- the radial currents are induced by coupling to the vertical, and the path between them is air.

But if you put the radials on or under the ground, some current flows back to the coax shield through the ground (eventually getting to and flowing in the radials). This causes I^2 * R loss, where R is the resistance of the path the current takes. Current is induced in the ground and the radials by coupling to the vertical portion. The current in the ground creates a field that induces current in the radials, and the radial current is collected at the coax connection.

An elevated radial system is between these two extremes. Most of the field from the vertical is "intercepted" by the radials -- that is, the vertical induces more current in the radials than it does in the ground. So the loss is lower than for ground level or buried radials, unless there are very many ground level or buried radials.

The idea of a "mirror" is an oversimplification that doesn't really have any physical basis. The signal from the vertical does strike and (imperfectly) reflect off the ground, but a little simple geometry shows that most of the low angle reflection takes place much farther from the vertical than most ground systems extend. So the radial ground system doesn't have much effect on the reflection, and therefore the pattern, except at high elevation angles.

1185. Why Do I Neen an Antenna Tuner?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-23 12:15:54 UTC
From: Al <ABurzynski@nojunk.satx.rr.com>
Message-ID: <_pwt9.195977$121.5526195@twister.austin.rr.com>
Source record: 132624

Does an antenna tuner improve the signal leaving the antenna or is it there strictly for the transmitter to see 50-ohms? For example, if I do not have a tuner and my transmitter, line, and antenna are all perfect 50-ohm and I transmit 100 watts, all of it is radiated by the antenna (not counting trivial losses). If I switch to a different band where the antenna is no longer the proper impedance, and I transmit with a not-too-high swr, the antenna radiates say 75 watts and 25 goes to (I don't know where). If I now add an antenna tuner and transmit the same 100 watts, the antenna radiates 75 watts and the tuner consumes 25 watts. I assume therefore that my signal output from the antenna was not improved in any way due to the addition of the tuner. Am I correct here or am I missing something?

Is the same thing true for receiving in the situation above? Will I improve the signal at my receiver with an antenna tuner or is the tuner simply consuming its share (25 percent in example above) of the signal?

In other words, why (the true reason for) do I need an antenna tuner for transmitting or receiving?

I appreciate all comments. Thank you.

Al

If you put an antenna tuner, this one will not "eat" the reflected power. At his turn, it will reflect the reflected power in phase with the forward power to the antenna so that finally the radiated power will be 100 w (minus a very small loss in HF bands depending on the SWR). See Maxwell book for a deeper explanation. He also explains why to put the tuner in the shack instead of at the antenna because there is very few difference (in HF certainly).

In reception, the tuner will act thus as an impedance adapter and will contribute to increase the signal level provided that the input impedance of the receiver is the same than the one at output of the transmitter. Sometimes it is easy to preset the tuner for transmission only in receiving. The tuner will also act as a filter (Low-pass or high-pass or band-pass depending of the circuit in use).

A tuner located at the transmitter end of the transmission line has no effect whatsoever on the behaviour of the line, the line SWR, or of the antenna itself.

The sole but essential purpose of the tuner is to ensure the transmitter is correctly loaded. (Usually with 50 ohms). It is an impedance transformer. It transforms the impedance seen looking into the feedline to the required transmitter load resistance.

It has nothing to do with any imaginary, confusing, so-called forward and reflected power.

Reg, G4FGQ

Source record: 132629

Al,
Antenna tuners ~can~ improve your signal by matching
impedances and letting your transmitter 'work' into a
load it 'likes', and so produce full power. Some of that
power may be lost in the antenna system (antenna and feed
line), but not because the transmitter is 'cutting back' from
an improper impedance match.
Most well built tuners have much less than 25%, closer
to 5-10%, or less, probably. If you exceed the tuner's
ratings/capabilities, naturally the losses will be greater.
I think that the assumption that 25 watts is lost in the
tuner isn't necessarily correct. That 25 watts may be lost
in the antenna system, but I doubt if it's in the tuner.
Tuners don't do 'miracles', they just match impedances.
'Doc

Doc,

I have measured the output power of my IC756 with and without the antenna tuner. When feeding a Hygain TH3MK4 the power out without the tuner is about 100W. With the tuner it is about 90W. The built in tuner is fairly low power. I suspect a 2KW tuner will have loss in the range you suggest due to use of higher Q coils. (Measured SWR was around 1.2).

The advice you received on the Butternut was excellent. You might go to the
Bencher web site, click on "Butternut" and read some of their tech papers.

I had good luck with a Cushcraft R-5, but it is no longer made.

Have fun...

There is a report published by Champion Radio Product titled "HF
Vertical Performance Test Methods & Results" by N0AX and K7LXC showing
field strength measurements they made on several commercial multi-band
amateur HF verticals. The results are interesting in that there was no
clear cut winner.

Considering the cost of some of these antennas I suggest it would be a
good investment in purchasing and reading this report before you spend
your hard earned $$. You can find more info at
http://www.championradio.com/

There will be some difference in the required length of ladder-
line.

> Will the 80 m dipole resonate at about the same point whether
> I feed it with 50 ohm coax or 450 ohm?

The 80m *dipole* will resonate at about the same point but the
antenna system will not. With 50 ohm coax, the feeder is not
tuned. With ladder-line, the system is tuned, i.e. the feeder
acts somewhat like a tuned stub and changes the system resonant
frequency, sometimes drastically.

> Don't I need a 9:1 balun to bring the 450 ohms down to 50 ohms?
> 450/50=9

If you use 450 ohm ladder-line on a 50 ohm antenna, the SWR will
be 9:1. If the ladder-line length is 1/2 wavelength, that 50 ohms
will repeat at the transmitter so no, you don't need a 9:1 balun.
All you need is a 9:1 SWR.

> After the 1:1 Balun is 50 ohm coax which you just screw into
> a 50 ohm jack on the tuner right???

I screw it into my transmitter - no conventional tuner required.
Varying the length of the ladder-line performs the tuning function.

> Is the 50 ohm coax length critical??

No.

> reflected power.

To expand a bit on Reg's post, on a practical level-

The tuner (when properly adjusted) matches your radio (on both transmit and receive) to your *antenna system* - the feedline and the antenna itself - such that the radio sees the proper impedance to operate as it was designed. Thus the system transfers the maximum possible level of RF on both transmit and receive.

Forget about SWR and just tune for maximum forward power. When you reach that point it will also be maximized for receive. That's the reciprocity of antenna and feedline systems. When it's tuned for transmit it will also be tuned for receive on a given frequency.

It is left it up to you to see to it that you use a feedline of good enough quality that it introduces losses that are moderate enough so that the RF moving toward (and from) your antenna is not seriously attenuated and arrives at the antenna (and receiver) substantially intact. Note that some losses are always present in every real-world installation and that almost all common coaxial feedline you will encounter is useable on the HF portion of the spectrum. The stuff does deteriorate some with time and exposure to the elements, but at HF it has to be pretty bad to become really useless. If you intend to minimize losses, use good coax. But realize that even as high a loss as 3db is half your output power, and that means only about a half an S-unit on the other station's receiver.

So one needs to keep it all in perspective. Would you stay off the air rather than suffer a half db loss on the other end of the contact?

Of course a poorly designed or implemented antenna won't work any better even with the best quality feedline. It will still be a poor radiator. But that doesn't mean it won't be useable to make contacts on

the air. Sometimes installing a good antenna just isn't possible. As someone said, a wet noodle will radiate RF, just not very well. And higher is almost always better. But many hams have done quite well with low, feeble radiators.
Been there and done that at times when it was necessary.

Also note that most modern radios need no help from the tuner on receive. You probably won't be able to detect much, if any, difference between a tuner/antenna and a random piece of untuned wire on receive. So the tuner is used basically to match your transmitter to the antenna system. The receiver would work as well without it.

ON5MJ wrote:
> The resonance of the antenna is not function of the length of the
> transmission line, excepted if the transmission line is unbalanced and feed
> a balanced load.

When the transmission line carries a relatively high SWR, the resonance of the *antenna system* is a function of the length of the *tuned feeder*. Feeding a resonant length dipole with 1/2 wavelength of ladder-line will cause the antenna system to resonate at the resonant length of the dipole. Any length other than a multiple of 1/2 wavelengths will cause the antenna system to resonate on some other frequency. Varying the length of the ladder-line feeding a dipole changes the resonant frequency of the antenna system.

> If your transmitter has no antenna tuner, it's better to adapt the impedance
> with a balun 9:1 in case you will use a 450 ohms line.

This is only true if the SWR on the ladder-line is 1:1 which it is not for a dipole. If the SWR on the ladder-line is not 1:1 (which it is not in this case) then a 9:1 balun is a poor choice since the impedance looking into the ladder-line will *NEVER* be 450 ohms. The possible impedances lie on the SWR circle on the Smith Chart. The center of the circle is 450 ohms and only exists for an SWR = 1:1.

Consider one pair of radials routed in opposite directions. The currents in
those two radials are out of phase and thus the fields cancel at a distance.
If you elevate those radials high enough, the fields cancel before they
encounter the ground and thus avoid a lot of ground loss. With the radials
laying on the ground, the fields don't cancel before encountering the ground
and thus there is a reasonable amount of ground loss so you need lots of
radials to try to mimic a perfect conducting plane.

Yes, if the antenna tuner keeps your transmitter from folding back
on its output power then that will improve the signal leaving the
antenna. Matching a system allows maximum available power to be
radiated (or received).

Well Reg, an antenna tuner keeps the reflected waves from
changing the impedance the transmitter sees to something
other than the 50 ohms into which it has been designed to operate.

If a transmitter is designed to put out 70.7 volts at 1.414 amps
in phase, an antenna tuner keeps the reflected voltage and
reflected current from superposing with those desired values
and changing them to undesired values.

Forgive my being so theoretically dense...but what about displacement currents and magnetic currents? Ground permittivity defines the quality of the capacitive dielectric, which defines the amount of image charge. "Good" permittivity doesn't transport conductive currents (J vector) but it does allow displacement (capacitive, D vector) currents. Burying radials affects displacement currents.

Would not elevating a radial system reduce the effects of poor ground displacement currents? Having two capacitors in series, to create the image charge?

Conductive currents (J) are far-field. Displacement currents are highest under one wavelength, and inductive currents (B vector) are highest, very close-in (under 0.1 wave). All three components add together.

Comments welcomed.

Welcome to Oregon - "The Food Stamp State"

1203. Modeling hose clamps, element mounts and gamma matches with NEC2?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-23 16:52:31 UTC
From: Scott <scott2rp789@netscape.net>
Message-ID: <3DB6D3CF.6F1318D5@netscape.net>
Source record: 132641

I have spent a great deal of time designing a 4 element yagi to meet my exact needs using NEC Win Plus+ (NEC2). I carefully remodeled the 4 element 12 meter Yagi from the ARRL handbook. Since I am reusing a old 4 element Yagi, I am accurately entering taper schedule. I am so happy with the design, I want to ensure the real world model is close as possible to what I've modeled and this has raised a few questions:

1) I want to use hose clamps so the elements are adjustable. Should I try to model these? Common sense tells me I would need to slightly shorten the elements...

2) What about the element to boom mounting plate? The plate is a 3.5" wide piece of aluminum with a 3/4" tube on it so that the 5/8" element passes through it. I modeled the 3.5" X 3/4" inner element piece, what what about the rest of the plate? This seems like it also might cause me to need to shorten the element length as well?

3) Lastly, I am going to use the gamma match that came with the antenna. I have 2 questions about this:
a) Do I need to compensate the driven element length because of the "shorting strap" and extra material added by the gamma itself? I just have a 50 Ohm source in the middle of the driven element and that's it.

b) The center of the gamma rod mounts offset from the center because of the mounting plate (it mounts 1.75" from the center). Should I try to rework this gamma match so that it taps in the center of the boom and element? Or can I offset the element in the mount so that the place where the gamma rod connects is the physically the center of the element length (I don't think so, but I'll ask)

Here is the manual for the antenna I am using:
http://www.majestic-comm.com/assembly/SUPPORT/M104C.PDF
It shows how everything fits together.

Thanks!

Scott.

Where did you measure this power?
1. At the transmitter output, prior to the tuner,
2. At the tuner output,
3. At the antenna?

I have two rigs with antenna tuners and often get completely different
power and swr readings at the rig (output of the tuner) and 2 feet away
with a meter in the feedline. {the meters were in the line before I
installed these rigs in case you were wondering why}.

The readings are identical when feeding an antenna which is matched to
the feeline at the frequency in use.

>
> 73 de ON5MJ - Jacques.

They don't. Four radials at 1/4 wave up are about equal to 50-60
radials on a ground mount. At 1/2 wave up, then yes, 4 radials are
about equal to a ground mount with 120 radials. The ground plane needs
less radials as it gets higher, because the base of the antenna moves
farther away from lossy earth. You can use only one radial at 1/2 wave
up and still have high efficiency, but you would have rather poor
decoupling from the supporting mast, and a slightly skewed pattern
from the lack of balance or symmetry in the radial system. Two radials
give a fairly clean omni pattern, but I recommend no less than 3
radials for a true ground plane antenna. Maybe others can give a more
scientific explanation.. MK

I used pill bottles, and glued the caps to the roof, then
screwed/locked the bottle onto the cap. When I left,
I left the caps in place. You couldn't even see them unless
you really looked very closely!

Dave,

The tuner is part of the radio, so I can't get at the point before the tuner. The meter was about 6 - 8 feet from the radio and about 75 feet from the antenna. When the tuner is turned off, relays inside the radio bypass it. Don't take the 10W differential as gospel. I didn't write down the numbers because I never use the tuner. I suspect it was no more than 10W.

wrote:

|I have spent a great deal of time designing a 4 element yagi to meet my
|exact needs using NEC Win Plus+ (NEC2). I carefully remodeled the 4
|element 12 meter Yagi from the ARRL handbook. Since I am reusing a old 4
|element Yagi, I am accurately entering taper schedule. I am so happy
|with the design, I want to ensure the real world model is close as
|possible to what I've modeled and this has raised a few questions:
|
|1) I want to use hose clamps so the elements are adjustable. Should I
|try to model these? Common sense tells me I would need to slightly
|shorten the elements...

Don't bother.
|
|2) What about the element to boom mounting plate? The plate is a 3.5"
|wide piece of aluminum with a 3/4" tube on it so that the 5/8" element
|passes through it. I modeled the 3.5" X 3/4" inner element piece, what
|what about the rest of the plate? This seems like it also might cause me
|to need to shorten the element length as well?

Leeson in "Physical Design of Yagi Antennas" has info on calculating
the equivalent diameter of various element to boom clamps.

You must consider not only the effects of the plate but that of the
diameter of the boom. The data summarized are a bit complicated but
I'll try to explain them here.

Let W = width of the mounting plate (3.5" in your case)

Let T = thickness of the mounting plate (?)

Let D = diameter of the element. (3/4")

Then:

A = (pi*D^2)/4 + T*W

P = pi*D + 2*(W + T)

the equivalent diameter of this is then:

D_equiv = ((A/pi)^.5 + P /(2*pi))

So you plop this into your model as the diameter of the element with
the length equal to the length of the PLATE. Whatever 3/4" tubing (if

any) that extends beyond the plate should be modeled as---you guessed it--- 3/4" tubing. If you are using the mounting method in the Antenna Handbook then this should do it. If you are using what is shown in your reference, it looks like the "plate" is really one-sided as contrasted to what Leeson uses. There is probably some difference but I seriously doubt that it is significant.

A rule of thumb (from Lawson's "Yagi Antenna Design") for the plate clamp is that the effect of the boom diameter is to reduce the electrical length of the elements by 6% of the boom diameter, which again is insignificant.

|
|3) Lastly, I am going to use the gamma match that came with the antenna.
|I have 2 questions about this:
| a) Do I need to compensate the driven element length because of the
|"shorting strap" and extra material added by the gamma itself? I just
|have a 50 Ohm source in the middle of the driven element and that's it.

No, the gamma adjustment procedure will take care of this. The gain and F/B are not a strong function of the driven element length. You don't need to be particularly accurate in determining the feedpoint impedance since you will be taking care of that with the matching system and gammas (IMHO) are not particularly easy to model.

|
| b) The center of the gamma rod mounts offset from the center because of
|the mounting plate (it mounts 1.75" from the center). Should I try to
|rework this gamma match so that it taps in the center of the boom and
|element? Or can I offset the element in the mount so that the place
|where the gamma rod connects is the physically the center of the element
|length (I don't think so, but I'll ask)

I would prefer to have the coax connector mounted on the boom. That is the electrical center of the element. Don't try to fudge the element off-center.

Have fun,

Wes

> the tuner. Am I correct here or am I missing something?

The antenna radiates all the power that gets to it (less any lost in the resistance of the antenna itself and ground system) regardless of the SWR on the line. If you put a tuner at the rig, all it does is to match the impedance of the rig to the impedance the rig is putting its power into. Modern rigs will put nearly full power into impedances corresponding to up to 2 or 3:1 SWR on a 50 ohm line, but if the impedance goes beyond that, the rig will reduce power. When that happens, a tuner is necessary to bring the impedance back to a value the rig can deliver power into.

A moderate SWR on a line of moderate loss doesn't appreciably affect the fraction of power that gets from the rig or tuner to the antenna. Very high SWR, or moderate SWR on a very lossy line, can increase the line loss somewhat. That's why open wire line is the choice for grossly mismatched antennas -- if fed with coax, the SWR can be high enough to noticeably increase line loss.

And by the way, if you lose 25 of your 100 watts somewhere in the process, don't lose too much sleep -- that's only 1 dB.

> Is the same thing true for receiving in the situation above? Will I improve
> the signal at my receiver with an antenna tuner or is the tuner simply
> consuming its share (25 percent in example above) of the signal?

On HF, you probably won't improve the signal. Effecting an impedance match at the rig will increase the *amplitude* of the signal getting to the receiver. But it'll increase the amplitude of the noise by the same amount. At HF, this noise is almost always much larger than the receiver's internal noise, so the tuner has no effect on overall signal/noise ratio. You can compensate completely by turning up the receiver gain control. If the mismatch is so bad or the antenna so poor that the receiver noise dominates, then a tuner will make an improvement by bringing the signal and external noise above the receiver's noise.

You can detect the condition when this is necessary -- switch from the antenna to a dummy load right at the receiver input. If the noise level doesn't change, the receiver noise is dominating and a tuner would help.

> In other words, why (the true reason for) do I need an antenna tuner for
> transmitting or receiving?

You need one for transmitting only if your rig reduces its power due to the mismatch. You need one for receiving only if the mismatch is so severe or the antenna so poor that your noise level doesn't change when you switch from the antenna to a dummy load.

Most likely, your transmitter will fold back energy output, if it looks into
an impedance different to 50 ohm.
Therefore, in an poorly matched situation, the energy available at the
antenna is not only reduced due to losses, but more significantly because
your transmitter does not deliver the energy, to secure survival of the
output stage....

Even if the match is correct, with aids of a well matched antenna at the
frequency, by a tuner or by other means, the radiated power may even be low,
f.ex. if the antenna is (too) short.

In my opinion, the tuner is only providing a match, so the transmitter can
deliver the RF energy. What happens thereafter is a different story....but
for a start, if rf is provided from the transmitter, you are likely to also

radiate a signal....

What has been your experience with these? From what I've read on the eham.net site they look pretty good. This months QST magazine had a write up on 'em too. It was positive. I'm in a residential area so my choices are rather limited. This one looks to fit the bill. Looks easy too. http://force12inc.com/sigma5info-003.htm

Is this a good choice for a newby's first antenna?

How is the performance compared to similar products?

Where do you have it mounted? On the ground sitting in a bucket like they suggest? On a pole? On the roof? On a pole by the fence?

Has anyone mounted one horizontal? If so how did you do it?

Any and all comments are appreciated.

Cecil, I've been reading your stuff on tuners, forward and reflected power for years, so far as I can remember without comment. Because I can't disagree with what you say.

But in connection with the purpose of tuners at the output of transmitters, to mention reflections, imaginary reflected power, conjugate matches, even imaginary SWR, is no more than a confusing and entirely unnecessary complication.

The tuner is just an impedance transformer containing 2 or at most 3 L and C elements which should be allowed to do its simple but essential job free from the interfering smokescreen pouring from this newsgroup. Its function can be described in un-cluttered isolation.

It's all very learned and convincing. <grin>

Yours, Reg, G4FGQ

Hi everyone,

Thank you for participating to my question.

I have noticed for many years that 4 radials (even 3) at 1/4 wavelength height are equivalent to 120 radials at ground level. OK.

But now, what about the EM field between the (few) radials and under the radials ? This is what I don't catch.

Their Sigma-SV5 looks interesting as well... basically the same as a
Sigma 5 but it doubles as a working TV antenna, and is just _barely_
short enough to fall within the FCC's OTARD rules (the ones which say
"Neither local zoning laws, nor CC&Rs, can prevent you from mounting a
TV antenna on your roof.").

Anecdotally - a guy brought a Sigma 6 to a ham-club meeting in my
area, recently, to show it to the other members. He was most
complementary about his performance, saying that he'd set it up in his
back yard that afternoon and almost immediately busted a pileup to a
ham operating out of one of the Antarctica research stations.

Haven't used one myself.

Reg, there exists a laboratory signal generator equipped with a circulator
which drives a dummy load. All the reflected power incident upon the signal
generator is tapped off from the system and is dissipated in the dummy load.
Would you be willing to grab a 100w resistor dissipating 100w of reflected
power and tell us that the blisters you get on your hand are imaginary? :-)

Consider the radials as a special case transmission line.
The fields from complementary radials cancel under the same
laws of physics as they do in a transmission line.

The field under the radials is the sum of the fields caused by the currents in the vertical and all the radials. Directly under the center, the fields from the radials cancel, and there is no field from the vertical, so the total field there is (theoretically) zero. Away from the center, the magnitude of the field depends on where you are.

You can get actual values of V/m and A/m with the free demo version of EZNEC from http://eznec.com. The accuracy of the result in this case won't suffer much from the demo's 20 segment limitation.

Source record: 132666

You need an antenna tuner to ensure the transmitter is operated with its designed-for load resistance, usually 50 ohms but within the range of 40 to 60 ohms is quite good enough and has little or no effect on tuner efficiency anyway. Conjugal matches have nothing to do with it either.

There's a tendency to severely over-estimate loss which occurs in tuners. The poor beast suffers repeatedly from unjust accusations by old-wives. The only thing they have inside to get warm is a few turns of very thick copper wire.

The following table estimates L-match tuner efficiency and overall radiating efficiency of the ubiquitous G5RV versus frequency band. Coil Q is pessimistically estimated at Q = 220. Antenna height = 33 feet.

Frequency	Tuner Effncy %	Overall Effncy %
1.9	70.1	1.4
3.8	98.7	70.7
7.1	98.7	71.4
10.1	97.7	42.8
14.2	99.9	87.7
21.2	98.8	66.7
25.0	99.9	84.6
28.0	98.0	29.0
30.0	97.3	34.7
50.0	98.6	52.9

With a 100-watt transmitter the tuner will run cold except on 160 meters.

T-match tuners always have marginally higher loss for the same impedance transformation ratio.

RF power measurements are notoriously inaccurate. Better estimates of tuner losses are obtained by running the rig at full power for a few minutes, switching off, and placing the palm of your sweaty hand around the tuner coil. If you are unable to hold it there then there's something very seriously wrong.

High RF power efficiencies are invariably most accurately estimated by calculation. Particularly when a small difference between two very high power levels is involved. If you are not vary careful a tuner GAIN can be obtained. Neither can you blow up the PA !

The above data, and much more, obtained in less than a minute using program DIPOLE3, downloadable in a few seconds from the website below.

Some NEC-2 based programs, like EZNEC, also handle stepped diameter elements for common Yagis. They use a technique described by Dave Leeson in _Physical Design of Yagi Antennas_ to substitute an equivalent constant diameter element for each tapered one. The substitution works very well, and actual pattern measurements of beams analyzed with EZNEC have corresponded very closely to predictions. You can, if you wish, manually apply Leeson's method to your model before running it on NEC-2, but it can be tedious. Programs like EZNEC do it automatically. But if you run a tapered Yagi on NEC-2 without the correction, you're just about sure to get a very wrong answer for the front/back ratio.

MININEC has its problems with Yagis, too. It produces an error when modeling Yagis with a relatively large number of elements, such as used for VHF or UHF beams. (The error probably exists with shorter beams but is too small to cause a problem.) The effect is that the pattern is about correct, but at an offset frequency. Quite a bit of effort by a number of people went into tracking this down, but to my knowledge no one found the cause. The original authors of MININEC also couldn't find the cause of this problem. I believe Brian Beezley, K6STI, claimed to have corrected it in his MININEC-based programs, but don't know of any objective evaluation of the correction's effectiveness, and he kept all details proprietary. I don't know whether the Antenna Model folks have found a way around it or not.

There was a long thread about this topic not long ago -- you should be
able to find it with a Google search. It prompted me to post several
tutorials on transmission line waves, including quite a bit about
forward and reverse power. I'm sorry I haven't prettied it up yet, but
you can get the postings in their original text format at
ftp://eznec.com/pub/Food for Thought/.

That's an interesting comment. To a great extent I disagree. I am aware of some very interesting empirical work currently underway in several areas. Additionally, I still think there's a certain art to the antenna design process in many instances.

>At the very least, this is a design GUIDE if not a

>

Recognize that the laws of physics also place boundaries on the design problem that limit genetic optimization in the exact same way that they limit the intuitive design process. Many intuitive antenna designs reach a point where they approach these limits. Genetic optimization may be of little value in these instances. Being able to simulate or genetically optimize does not, in and of itself, guarantee that a more optimal solution is obtainable.

Simulation packages and genetic algorithms/optimizers are tools. The effectiveness of a simulation package and a genetic algorithm as a design tool are many times only as good as the design experience of the programmer or the person using them. The genetic algorithm still needs to be set up with some pre-defined starting point, boundaries, and methodologies that dictate how the evolutionary process occurs. The design intuition of the programmer is an important part of this process. It is my opinion that a person with no antenna design experience and no experience with the simulation routine used by the algorithm would not put a very effective antenna design genetic optimizer together.

I'm not sure what you're implying here. Why would you ask me to engage in a debate and then complain that your time is too valuable to participate? You challenged me to a public debate many months ago and almost begged me to participate as "you needed closure". I finally accepted and offered a simple challenge as a focal point for the discussion. You indicated that you wanted an FOM to work with. I provided the FOM quite awhile ago. Now you seem to be delaying the process asking me if I want to change the FOM. I don't. Provide an optimized design whenever you can. If you don't have the time for this, we can end it right now.

Then do what I do... install "N" connectors that are clamp mounted. (Or BNCs on 8X.) At the antenna end, install an appropriate adapter, and weather seal the 259 portion. Connect/disconnect the N connection, and don't bother weather sealing it; N connections are already weatherproof.

Yes, it adds a few bucks to the total cost, but compared to the cost of replacing the coax because water gets in it, the added cost is negligible.

If you're using an external wattmeter, the reading with the internal tuner engaged (90W) is probably incorrect. This is because the wattmeter is accurate only at its design impedence (50 ohms), and with the tuner in line, the impedence on the feedline can be anything.

I had an old TS-440/AT that would show 130W on an external meter on 10 meters when feeding an unmodified CB antenna. (The internal meter showed 100W.)

I have a Butternut HF9V and am very happy with it. My QTH is in Central New Jersey and I worked 9K2GS, Abdullah in Kuwait City last Friday night. Not only did I break the pile-up; but Abdullah stayed around to chat for a few moments. He asked me what I was running; and I told him 100 watts from an Icom IC-751A to the Butternut. He seemed to be amazed! He said my signal was really loud and outstanding. Never heard THAT from a DX station before! This made me happy, to say the least.

I used to have a GAP Challenger at my old QTH before I got married and moved to the present QTH. I was never quite liked it. The results weren't much better than the G5RV I was running; and that GAP was quite whippy in stormy weather. There were a few times in windy weather that I held my breath as I thought it was going to self-destruct. Amazingly, the Butternut is not like that at all! Maybe it's the different QTH; or maybe it's the way it's made ... I don't know. But I do know that since I've put the Butternut up, it has worked great and I haven't gotten any gray hairs worrying that it was going to collapse on a day when we get high wind warnings.

I've had one for a couple of months. By far the best antenna I've had to date that will fit in my severely limited space.

> Is this a good choice for a newby's first antenna?

I would say so. You'd have to work at it to screw up when putting it together. You may have to tweak the tuning on 20m, as nearby metal will detune the antenna. (Word of advice... put the cover back over the coils when checking the SWR, as it does affect tuning.)

> How is the performance compared to similar products?

Excellent. Since it's a vertical dipole, you don't have to futz with ground radials.

> Where do you have it mounted? On the ground sitting in a bucket like
> they suggest? On a pole? On the roof? On a pole by the fence?

Mine is in a bucket of concrete sitting on the flat roof. Force 12 recommends ground mounting; if I could do that, I would, slipping it into a piece of pipe driven into the ground.

> Has anyone mounted one horizontal? If so how did you do it?

I haven't, though I've read about such installations on the net.

> Any and all comments are appreciated.

I love mine, and will probably continue to use it even after I move, and am able to put up a beam. Given its ease of disassembly and small size when disassembled, it'll probably travel with me.

1240. New program OSCTRACK.exe

NOW AVAILABLE ** New Program "OSCTRACK.exe"

Tracking of RF signal and local oscillator tuned circuits in superhet radio receivers.

The program calculates all L and C component values and then checks tracking error as the two-(or more)-gang tuning capacitor is varied from the keyboard from one end of the band to the other. Covers all signal frequencies from VLF to UHF for any Intermediate Frequency (IF).

Ideal for receiver home-brewers.

Download in a few seconds from website below and run immediately.

Dave,

Get some penitrating oil and sok the bolt and nut in it. If you have to
use a rag or old paint brush to apply it for two-five day if needed.
I used to sok nuts and bolts in a can of penitrating oil for a week,
only because I was getting back to the barn the next week.

LPS Product makes a 12oz spray can. I know DoALL Industrial Supply,
Granger, and other places sell it.

Scott,

40Mtr during the day and 75Mtr at night. ARES and RACES Nets.

40Mtr is not great after 1pm for me in Central Calif or Nevada. AM is
best and quieter. Look out for the Broad Cast Stations at night and
Early AM. Now that I have my Extra I can get away from them.

10Mtrs in the summer is good at 5pm Pacific Daylight Savings Time.
20 might be better for you with the space problems you my find you have
to get somthing on 75Mtr

Enjoy. I am in the works of a Horizontal Loop on the roof or in the atic.

No. It's calculating an equivalent diameter for that length of
element, whatever the length of it.

If your plate is 3.5" in length then you model that portion of the
element as 3.5" long, 2" in 'diameter'.

Wes

[snip]

You stated that you would do it. I believe you stated it would be done by
mid-October 2002, well now it's almost November.

Dr. Best has expeditiously supplied you with a very explicit FOM.

Now... just cut all the USENET posting bull, simply fire up that GA
optimizer of yours and get going on antenna design.

You claim to be a "scientist", but now [IMHO] it seems that you just post on
USENET, rather than do actual quantative design.

"Just do it!"

That's right... with a balanced feedline SWR doesn't seem to make much
difference to actual radiated field strenth.

I use a 80m loop with a tuner with open wire feeder and do extremely
well.....

Considering a transmit antenna system, if the Z of the transmission line is not matched to the input Z of the antenna it is connected to, the antenna will reflect some of the power in the line back to the transmitter (tx). What happens then depends on the Z match of the line to the tx. If Zs are matched there, the reflection is absorbed by the tx and dissipated as heat. If is not well matched, some is reflected back up the line, and some is absorbed by the tx. Of the part that may be reflected back to the antenna, some will be radiated and some will be reflected, just as in the first case. This dual process continues until the power generated by the tx is dissipated by some combination of radiation and absorption.

The best place to install an impedance matching transformer (tuner) is physically as close as possible to the impedance mismatch it is intended to correct. A tuner to match an antenna that is installed at the antenna input will effectively remove the standing waves on the transmission line, because then all the incident power will be radiated, and there will be nothing left to reflect back down the line.

> And by the way, if you lose 25 of your 100 watts somewhere in the
> process, don't lose too much sleep -- that's only 1 dB.

dB = 10*log(25/100) = -6.02dB

Here's a recent example:

100w XMTR----50 ohm feedline---x---1/2WL 150 ohm feedline---50 ohm load

There is a 4:1 SWR and 33.33w of reflected power on the 150 ohm feedline.
Where is the reflected power that is "absorbed by the tx"?

A tuner prevents reflected power from reaching the transmitter. If no
reflected power reaches the transmitter, then no reflected power can
possibly be "absorbed by the tx".

What we have here is a failure to communicate.

The "width" is the dimension along the axis of the boom. The "length"
is the dimension along the axis of the element.

Answer the question as posed: is this the FINAL form of the FOM which, to the best of your ability, is not an ill-posed formulation, but one designed to --distinguish-- physically meaningful candidates in an optimization scheme? Are you convinced that it has no pathological behavior? Are you convinced of its validity?

I will not discuss it any further. What I expect from a scientist is: 'here is the best formulation I wish to proffer upon an objective and thoughtful review and conference with colleagues.'

Are you saying this?

Cordially,

NC

Source record: 132602

Hi Al -

Let's assume that you are talking about an add-on antenna tuner applied at the sending end of your transmission line. Then the short answer is:

If your rig can accommodate the impedance seen at the sending end of your transmission line, then NO, you DON'T need an (external) tuner. Your rig should tell you if you need one. But do "ask the question" at the lowest practical power level, so as to avoid damage.

Given that, a couple of other points (in no particular order):

1. One post refers to rigs starting "high" SWR power-limiting at SWRs above 2.0:1. Perhaps some rigs work that way. But my rice-burner starts limiting at 1.5:1, which I think is fairly typical. (However, it does have a built-in auto tuner, which will work up to 3:1 or so.)

2. Some posts suggest that a tuner dissipates no power, or completely negligible power. How about a little rocket science on this one: If tuners are lossless, why do the ones rated for high power need to be bigger, with lower-loss/higher-dissipation components? Duh! (Please forgive if I sound a little waspish on this.)

The March 1997 QST compared four high-power tuners of the time. When working into SWRs below 4:1 or so, and when in the more favorable frequency bands, these tuners tended to have negligible loss. (There was one exception, a tuner that never seemed to get under 10% loss.) In the less favorable bands, most of the tuners had losses between 10% and 25%.

I agree that a 10% to 25% tuner loss is not going to make much difference at the receive end. The main concern would be that the tuner not get too hot, and become damaged. Note also that if your tuner has these losses trying the buck a high SWR, there are probably additional losses in the transmission line itself, because of the high SWR--at least with coax. So it's a really nice thing when the antenna and feed line are well matched at the antenna.

It is also my belief that SOME of the folks who give tuners a free pass for 25% loss would be absolutely apoplectic if a similar loss occurred in something they didn't like--e.g., the termination resistor used in some broadband, no-tuner antennas. But that's OT...

> 'Doc

Pretty close. But just a tad bit long. Depends how you want to design it I guess. Some prefer a shorter 5/8 to give a slightly cleaner pattern with a better null overhead. IE: MW broadcasters, etc.. 587/f is pretty close for that. If you wanted to use .64 wave as the length, 599/f is pretty close. For a vertical, I'd probably use the 587/f. For an antenna like an EDZ where it might be preferred to get the most gain available, 599/f might be better. You can use 165/f * 6.25 to get the loading coil value for a non grounded coil. 305/f * 6.25 for a grounded base coil. The results would be in microhenrys. MK

Thanks for the report. The problem might have to do with the name of the subdirectory. It contains spaces, and people might not be aware that names are case sensitive, at least on Unix systems. I've changed the name of the subdirectory to food_for_thought, which might help. Try going to ftp://eznec.com/pub/, then selecting the food_for_thought directory when you get there. You should also be able to get to the ftp pub directory by going to http://eznec.com and clicking the "ftp site" link near the bottom of the page. Please let me know if you still have trouble accessing it, and anyone else having trouble please let me know.

Roy Lewallen, W7EL

Hi Fred,

You should, by now, have been able to follow the grist of the
challenge offered, accepted, and avoided by now in the thread Antenna
Optimization. You may also observe the quality of "standards"
employed to NOT do anything as I had observed in that same thread.
However, I do have to admit that my 5:1 ratio was out of whack to the
demonstrated 8:0 response offered:

As pointed out in the past, this charade is for commercial purposes only and any suggestion that this proposed challenge or debate (as it has been charmingly described by the tight lipped, disfunctional party) will go forward to a conclusion is simply more (albeit lame) marketing hyperbole.

The character of the challenge has been met twice with simple responses to be rejected with this flood of bewildered questions of a naif demanding answers. [Our community is not surprised by the jejune attitude of the poster and find the contrast to claims of scientific achievement, publication in vanity rags, a source of endless amusement.] If and when they are answered, we can expect the continued speculations of "scientific" methods only Nostradamus would examine:
9.) Are you sure that blue is not more appropriate than #12 wire?
10.) Can you provide the names of 12 tenured professors of RF that concur with your choice?
11.) Were you standing when you posted your FOM?
12.) Were these same tenured professors standing too?
13.) On which feet?

14.) I expect a responsible scientist to respond immediately with the appropriate response to this request - will you do so?
15.) Too late. Immediately meant between 14 and 15, not after - how irresponsible and inappropriate of you.

So, Fred, can you see the genesis of the flame and how it builds to a conflagration? This low-brow humor injected by fraudtenna in the place of actual results is about the only (and meager at that) content available in that rapidly decaying thread. Such "science" is in desperate need of hamburger helper.

We are often regaled with humorous postings from the nut fringe who want to proclaim their advances in science, but come to us asking for an explanation as to how it works. They then select the correspondent who comes closest to parroting their nonsense and exalt at their being anointed masters of the universe (or of merely a small planet at the edge for the eh community - they are more humble than most).

And, as you may also tell by now, I love these opportunities to add to the festive occasion by holding this open casket ceremony. Do you have any comments to pass on to the other side before we drive the stake in?

Hi,

Has anyone use the Extra tapered whips for the hamsticks? I am wondering whether they are supposed to increase radiation efficiency? There seems to be no info available about them. From www.hamstick.com website:

a.. TW-1 Extra 47 inch tapered whips $5.95
a.. TW-2 Extra 59 inch tapered whips $6.95

Any info on experience is appreciated.

Thanks,
Andreas, KU7T

1273. Figures of Meri t(FOM) and Optimization

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-24 19:52:09 UTC
From: Fred Marshall <fmarshall@acm.org>
Message-ID: <ap9j4u$29b2$1@feed.centurytel.net>
Source record: 132612

There have been threads here that discuss figures of merit for antenna design. In some cases the discussion seems to be narrowly focused - as if there were a single FOM that would / could apply in a design process.

Well, sometimes there is a single FOM that would apply to a product or design. For example, there's a well-accepted FOM often used in passive sonar or radar: FOM = SL - NL +DI - DT

where SL is the signal level, NL is the noise level, DI is the directivity index of the array and DT is the detection threshold in the receiver.
And, there are similar ones for active sensors and for radio communications as everyone probably knows.

So far, so good.

I wonder if the term FOM as used above isn't sometimes confused with with what might otherwise be more appropriately called the optimization scheme's "cost function" - the thing that is to be minimized or maximized in a design optimization scheme. (I don't really like the term "cost function" but it's the most common term I believe).

Now, what happens when we are doing an optimization? We can still use simple system figures of merit as above in talking about the design that results from an optimization. However, in doing the optimization we also usually need to introduce the design criteria and contstraints in addition to such a figure of merit. So then we would talk about a cost function that combines system performance with underlying parameters. Generally, this requires that there be a combination of results. The most typical is a simple sum of the results stuck into the optimization such as:

Minimize: 0.4 x array sidelobe level and F/B ratio measures + 0.4 x beam width measure + 0.2 x size of the array

- and you can include whatever you like or are able in the combination expression
- and you can use expressions that aren't simple weighted sums

What's important here is that the 0.4, 0.4 and 0.2 "weights" are usually numbers that have been arrived at arbitrarily - they are subjective.
In the real world, we may even have to tweak them after getting optimization results - as we learn.
My final weights and your final weights may well be different for the same optimization.

Also, multiple designs can have the same FOM as used at the top of this message. Usually optimizations try to arrive at a global optimum - which would be a single result. I say "usually" because some optimization schemes use a blind search that don't guarantee reaching the one and only best result - it depends on where it starts and so forth....

So,
- FOM (as above) isn't unique (although the optimization cost function may be)
- optimization cost functions are often subjective

What's the point? Well, it's not that FOMs aren't useful, because they are. The point is we can get all confused if we mix a system or design FOM with an optimization cost function. They aren't the same thing in general. Here's a simple example where they are almost the same:

FOM definition: SL - NL + DI - DT

Cost function definition:
maximize [SL - NL + DI - DT]=FOM
minimize 5*DI - 10*DT where 5 and 10 have been selected subjectively / are in that sense arbitrary
subject to:
array size less than or equal to 5 feet in its maximum dimension,
DT is not less than +10dB,
SL=120dB and NL=-120dB

So, when we talk about optimization of a mix of antenna characteristics, it means that there will either have to be:
1) Optimize a system FOM all by itself - generally to maximize it. But the one above for a passive receive system is a simple sum so there are any number of individual values that will satisfy it.
2) Optimization of a cost function that's more complex - which means deciding on the weights. This means that it's arbitrary.

Well, I hope this is helpful or at least thought provoking. Comments?

In that case the tuner is matching the net impedance of the line and antenna
to the tx, and power transfer is maximized. Without the tuner, the tx
PA/output network (and line) can dissipate part of the reflected power.

I kinda got into this thread late but......

I've owned a Titan for the last 15 months and it has performed very well. Assembly was a bit hard (lots of parts) but it went together ok. Installation was SCARY! the antenna was mounted on a 15' pole and when I pushed it up from the horizontal position, it really bent over! I had installed 3 parachute cord guy lines at the gap so it has remained quite stable despite the crazy Kansas weather we see here.

I've only had two problems:

1) It dosen't like 50 foot lenghts of coax - I tried 50 foot and got high SWR's. I then added 10 feet with a jumper cable I had and bingo - it worked.

2) I ran into high swr's on 40 - I traced this problem to the position of the loop part of the antenna - after moving it slightly, the SWR's came back down.

Performance has been exceptional for both local and DX contacts. I have a friend (N0JVT) that has an indoor 15 meter dipole and lives across town. With 100 watts and a swr of 1.4:1 I hit him s9+25. Noise levels on the antenna are great - much better than most verticals (I've tried quite a few).

Enjoy your GAP - it's a fine antenna, worth the $$$.

Hi Fred,

I think in the 6Sigma program this is also called "risk analysis."

Your differentiation of cost and merit is useful, but using the terms "subjective" and "arbitrary" without context weakens the discussion.

First, Cost is not cost in a literal sense (or simply dollar$, that merely returns us to FOM). Cost is expressed largely in intangible terms and is a personal burden, hence its subjectivity. That we should reduce ourselves to abstractly numbering our grief makes it arbitrary. However, through this introspective process one divorces the notion that there is a bookkeeper's solution (FOM) that guarantees success; and allows the intangibles (for a fuller reckoning of Ccost) back into the equation.

Problem with this metaphysical approach is that it remains mechanistic and as deterministic as found in the FOM reduction. And, as these FOM mentioned already carry Cost provisions; I would say they have been crafted well enough by Steve to proceed. I would also say that Steve has painted the bull's eye around his own arrow - by invitation - and the host is welshing out with feigned alzheimer's (or is it Fawlty Towers?).

Richard,

Re: 6Sigma / Risk Analysis ... interesting. I can surely see where it would apply.

Re: "cost function - cost is not $$cost"
Yep, that's why I said I didn't really like the label.
But, you did catch the point about it departing from bookkeeping!

Mechanistic - yes. But I don't think of it as so "deterministic". Example: I set criteria, look at the result, modify the criteria because I wasn't as well informed prior to the previous step. There are iterations that the computer can do alone and there are iterations that are helped by human observation. I've used this method in best dealing with transition band wigglies in filter design. Of course, the software has to accomodate some change to do this.

I wasn't trying to personalize it. Too many discussions for me to go back, read, study, ponder, etc. So, I was hitting on what seemed like could be a confusion factor all 'round. Simply that standard use of "system FOM" and

use of the term "FOM" in an optimization context are really referring to what are two different things (usually). Mixing them together in discourse is probably not a good idea.

Hi Fred,

Your comments are well taken. In many years of antenna design, FOM has not been something that I have used - ever. I think most of us work within the boundaries of a complete set of performance specifications and then optimize the design based on well understood performance trade-offs. This could be viewed as a do the best you can everywhere approach but it seems to be universally accepted and understood. I can't recall a single customer in my military or commercial antenna career ever specifying an antenna with a single FOM using a weighted performance algorithm. Your comments on the sonar and radar are noted.

The FOM concept, while perhaps useful in some ways, seems to have some inherent flaws. In many cases, customers don't really understand how antennas work nor do they really appreciate the trade-offs involved in the design process. Most customers specify bandwidth, SWR, gain, beamwidth, polarization, etc and you do your best. Imagine the blank stare you'd get telling the customer that you did not meet his gain spec but you exceeded his bandwidth requirement so that the FOM came out good.

As you and Richard stated, FOMs are a very subjective issue.

Steve VE9SRB

I was unaware that you required a Best and Final FOM before you could
proceed.

I provided the requested FOM a month or two ago. You said you would respond
with an optimized design in October.

The FOM stands as originally posted. What is the expected delivery date of
the optimized design?

My guess is that they are replacements for missing or cut-too-short whips.

Fred,

For the most part, the NG is very interesting and a lot of informative
discussions occur.

A good analogy is television: sometimes its like watching the Discover
channel and you learn some neat things. Sometimes its like watching
Seinfeld - it never makes sense unless you simply appreciate the humor in
it.

Also some use the longer whips is a higher frequency coil to make a longer
and more efficient antenna.
Like using a 20m ham stick on 40m with a longer whip.

Please read what you said again. You said "if the Zs are matched the reflection
is absorbed by the tx. If it is not well matched ... some is absorbed by the
tx." I pointed out a case where none is absorbed by the tx.

Gentlemen,

Thank you for your comments (although a little heated in spots! All are friends in this group, right?). I appreciate the info and the references for additional reading. I'm going to need a little time to try and digest all this, but I believe I get the basic ideas. I just purchased the ARRL Antenna Book, perhaps this will throw some good light on the subject.

My present rig is an older Icom IC-745 which puts out about 70 watts max. Maybe I don't even need to worry about a tuner, but I prefer to be safe and not blow the rig. Thanks again.

1289. Collins Radio Antenna Compendium

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 01:44:01 UTC
From: "Harold E. Johnson" <W4ZCB@mchsi.com>
Message-ID: <Bl1u9.93857$%d2.35093@sccrnsc01>
Source record: 132428

Long ago, long before the League used the term, Collins had a small spiral bound book with a blue cover and it was named the Antenna Compendium. I had a copy, but donated it to a local Ham library which has since become non-local.

The book contained a section on electrically short verticals and showed a nomograph regarding radials. To my recollection, it indicated that for a given length of wire, you were better off with a few long radials than many short ones. I can't find that replicated in any form in Jasik, would someone out there by any chance have a copy of the Collins book and could refresh my decaying memory? I'd be happy to reimburse any costs to duplicate those 2-3 pages or a .PDF would be super.

1290. Re: Figures of Meri t(FOM) and Optimization

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 02:14:24 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <apa9e1$4u9$1@slb6.atl.mindspring.net>
Source record: 132429

Fred, Steve, Richard, et al:

To clarify...

In the context of this thread and its' predecessors, the Figure of Merit [FOM] requested by Dr. Cohen is [apparently] indeed intended to be used directly as the "objective function" in a Genetic Algorithm optimization routine. Here the term objective function and FOM are both used in the sense of classical mathematical optimization techniques.

As Steve has alluded in a recent post, and as Fred has pointed out... an "objective function" is usually always required by computer optimization routines in order for such routines to have a quantitative and evaluateable [is that a word?] "objective" to minimize [or maximize as the case may be].

In Dr. Cohen's case since he has thrown down a challenge and has proposed a design competition between his [apparently proprietary] Genetic Algorithm powered by a cluster of microcomputers and Steve Best's best intuitive/manual designs.

This recent challenge [Along with the request for a quantative objective function/FOM.] was/is in direct response to a somewhat embarassing challenge thrown down last year by Dr. Cohen to this whole USENET NG [Along with a $1000 prize which was never paid!] in which Dr. Cohen's best GA/fractal antenna design was beaten hands down by simple arbitrary geometry antenna designs proposed by Steve Best. In fact Dr. Cohen has been making rather extravagant claims for the superiority of fractal antennas over all other designs for several years on this USENET NG. Even though there are clearly an infinity of [non-fractal] geometries which could equal or exceed the performance of any given fractal antenna design. This approach and series of challenges is apparently an effort to help secure some kind of supposed intellectual property/patent position which is claimed by Fractal Antenna Systems or Dr. Cohen or both.

The question as to the relevance or true meaning of a mathematical objective function constructed and supplied as a function to a computer routine [Genetic Algorithm or any algorithm for that matter] as a design requirement is an entirely different manner.

To paraphrase an old saying [beauty is in the eye...] it could be said that "the beauty of an objective function is in
the eye of the designer".

Because of the aggressive and sometimes absurd challenges and proposals of Dr. Cohen for his fractal antenna
design approaches and apparently proprietary genetic algorithm mathematical optimization techniques and
multi-megaflop computer expoits and his embarassing defeats at the hands of simpler design methods, he
now appears to desire to recoup that ignominy with a pure effort at maximizing/minimizing a mathematically
constructed objective function.

Well Steve Best being no shirker has indeed given Dr. Cohen his quantative objective function, and it matters
not a whit as to its' suitability as a design objective.

It's just a contest of antenna design gladiators.

The Cyborg versus the Man.

GA/fractal/super-computer versus a single man with a good eye for design and a slide rule.

The Scientist versus the Engineer... Fractals versus arbitrary geometry.

Dr. Cohen has his FOM... I say let him stop fussing, he's lost these design competitions in the past. If this
NG had been the Roman Collesium, then Dr. Cohen would have been dragged out along with the bodies
of the Christians eaten by the wild beasts. But no... he keeps coming back.

Now... let the games begin.

The rest of the "mob", er... NewsGroup will sit here in the stands and watch the carnage.

Anyone taking bets? I'll ante up 1000 drachmas myself for the arbitrary/slide rule approach.

Best,

1292. Converting a G5RV to a Delta Loop

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 02:38:23 UTC
From: rcuffee@hotmail.com
Message-ID: <df27559b.0210241838.7aae8f6b@posting.google.com>
Source record: 132431

I have a G5RV jr (52 feet 10-40 meters), and I have it installed as an inverted vee at 35 feet, the ends are about 15 feet off the ground. If I add 35 feet between the ends of the G5RV to creat a delta loop, would this improve the performance of the antenna? Currently I can tune on 10-40 except 30 meter using the rig's ATU.

Thanks,

RC

You have now given your final word on the requested figure of merit.

The 'failure' or 'success' of any optimization--whether it is conducted by a person or a machine--is only as good as the UNDERSTANDING and the INPUT so provided.

Thus, I expect you will accept responsibility for any failure--if there is one or more--if the problem so pursued is ill-posed and NOT scientific in its methodology.

I did my best to alert you. My conscience is clear.

I will run the analysis in early/mid November and a full analyses will be publicly disseminated on www.n1ir.com sometime after Thanskgiving.

I will remind all interested parties of the existence of said analysis and critique after that date. I will be obligated to cite it when any relevant issue arises on 'Steve Best' and fractal antenna work. This is not in any way meant nor intend as a personal attack, but a clear and objective statement of facts, all presented as knowingly true.

If there are statements which are not factually accurate presented, in error, I will be happy to correct them to indicate the truth.

The analysis will be conducted in early/mid November, and then posted on a web site, after Thanksgiving, for rapid and global dissemination.It will be on www.n1ir.com then.

I trust you, as myself, will make efforts to let the antenna community as a whole know these results. It is important that such a clear example of how a problem is pursued, and what it means, be made widely available.

I have full confidence that this will close the final chapter in the so-called debunking of fractal antennas. I will then place all public efforts on IP enforcement, which is the real issue.

BTW, did you see Dr. Rahmat-Samii's press release? I thought it would interest you. It interested me:

http://www.sciencedaily.com/releases/2002/10/021022070904.htm

While you've been busy as a bee trying to debunk fractal antennas, Dr. Rahmat-Samii seems to be claiming a curious status with respect to the field.

It's good to be retired from academia. It gives you a fresh perspective.

Best,

Chip N1IR

Performing random modifications to a working antenna usually results
in less performance. Why not download the free demo version of EZNEC
from http://www.eznec.com and see for yourself.

1296. Yaesu ATAS-100 Problem

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 03:44:09 UTC
From: Jack Leishman <k8xx@gtii.com>
Message-ID: <urhffe2qsr1ba7@corp.supernews.com>
Source record: 132435

I bought an ATAS-100 and it never worked properly. After emailing Yaesu for help, they offered only a new base section for about $160.00 plus shipping. The problem I was having was an open circuit from the bottom ground to the next ground up about about 3 inches located at the circuit board. An ohmmeter easily confirms this problem. The bottom most 3 inch section is RF open, but a DC path for the motor control circuit. It probably has a an RF transformer of such, but it is a sealed unit and no information is apparently available for it. The antenna is usless with the DC path open. I found that winding 22 turns of insulated # 16 wire around the lower 3 inch base section corrects the problem and the antenna works as well or better than original. It is necessary to drill and tap a new 8-32 screw hole in the bottom ferel and connect the top of the coil to the screw already in place. Wrap tape or shink wrap the coil and you are back in business. I soldered ring connectors on both ends of the coil.....it sure beats paying the big bucks.....I had the stuff in my junk box. It works very well on 40 as I suspected in may not have enough inductance at that frequency. 6 meters tunes very well and radiates good as well. I haven't compared it against the original, but from an operational; point of view it seems to work better than ever, as mine was apparently bad from the start I have no benchmark. Feel free to pass this on as I hope this information helps others in this same situation.....jack k8xx
PS.... I have learned that DC controls voltages below 10 volts cause the antenna to move one direction and voltages above 10 volts cause it to go the other direction. Also use Google to search for other helful hints on the antenna.

Do you mean that a single design produced by a genetic optimizer to optimize a single numerical figure of merit constitutes final and convincing proof that fractal antennas are superior to all other types of antennas of equal size, as is often claimed or implied?

Scientist, indeed.

>
> Steve VE9SRB

Steve,

I think we agree in principle. But, with all respect, I'm afraid I can't agree if I'm to maintain the context set forth - which I do feel is important. That was, the term "FOM" is best left as a measure of system performance as in the example given. And, the term "cost function" is something with a different meaning. (I might have used the optimization term "objective function").

I didn't say that FOMs are subjective. I said that "cost functions" (or "objective functions") are often subjective. I tried to make a distinction between the two because I'm suggesting that it helps to differentiate what we're talking about.

Oh my! I just noticed a terrible accident / play on words: the "objective function" is often subjective. Yep. I don't imagine we should try to invent a new term though such as "goal function". :-) But, I digress.

In the context that I was trying to establish, "real" FOMs are of a very objective type and one may find them quite useful. For example, antenna gain to noise temperature ratio G/T is often used as an antenna or receiver figure of merit. Nothing subjective about that. For Yagis we often see the front-to-back ratio alluded to as a type of figure of merit for directional arrays. Also, not at all subjective.

I also gave an example of why this type of objective FOM was different from an optimization "cost function" or "objective function" - which is really a misnomer because the "function" may well not really be a function but a conglomeration of constraints, weights and measures.

I'm sure the customer would be happy if you said you'd met all of the specifications within the constraints and, oh by the way, the G/T of the antenna is X. Or, perhaps better still, that the specified FOM of the antenna (as in G/T or F/B ratio) was exceeded while meeting all of the other spec's and constraints. This works as long as the "FOM" we're talking about here is something simple like G/T.

At the same time, I'm sure that the customer would yawn if you said that you needed to tweak the objective function weights in your favorite software tool three times in order to achieve the wonderful design reported above. In fact, the customer would yawn about any of the details of the process that you used in reaching the design. So, if you designed the antenna by the seat of your pants through some intuitive process that would also be equally off topic. But, it might be interesting!!

So, with that small objection / clarification about terminology I hope we agree.

I am using a Yaesu VR5000 communications receiver.
to monitor all the ham radio bands. I have no problems hear.
I use a random long wire with a yaesu FRT-7700 ATU.
the receiver goes from 0.1 right up to 2599.99998MHz.
with the following bands /cw/ lsb/usb /am / am-n / am-w/ fm-n/fm-w/
I want to try listening to space communications.. and would like some advice
from you ham radio experts....I want to get the best possible use from my
receiver and want advice on antennas...I don't really want to go down the
road of beams and rotors I want to do that later if I pass the foundation
licence.......can anybody give me advice on what is my best antennas to use
at this time I am using long wire and a standard discone.
but want to listen to space coms and anything else higher up in the
frequencies....please help thanks email your help to me at
shogun1965@lycos.co.uk

John wrote:
"I am using long wire and a standard discone, but want to listen to space coms and anyhing higher up in the frequencies."

John`s receiver limits, he says, his reception to less han 2.6 GHz! For higher frequencies, he will need another receiver or converter.

A discone works over several octaves well, based on its size. It is vertically polarized and has a null at its zenith.

For best performance from 0.1 MHz to 2.6 GHz requires several antennas. To listen to space coms may require several antennas, and reception from nearly directly overhead where the dscone has a null. A crossed dipole (turnstile) may be better for zenith rception, or an array of such antennas may be needed for more gain. The array cramps the non-directional style.

A wire 25 to 50 feet long placed as high as possible may get shortwave signals well.

For medium waves and low frequencies, groundwaves are vertically polarized, so only vertically polarized rods and loops, and vertically polarized "wave antennas", are effective.

In noisy locations, balanced, horizontal antennas pick up less noise on HF bands.

=========================================

What is never mentioned in this context is that horizontal antennas also
pick up less signal coming in at low angles, the best of the DX. One must
be careful not to throw the baby away with the bathwater.

Not so. My SGC 230 works just fine in a balanced configuration, with choke
balun coils in the coax _and_ control cables. No significant RF in the shack.
No problems for the SGC. It tunes my random length dipole (~100ft) on all
bands. If there is a good balun I don't see how the SGC can tell which side
is ground, because neither is.

A delta loop doesn't work against a ground, does it? AFAIK it's a balanced design.

Dick wrote:
"If I install a loop in my 24`x35` (horizontal) attic will the radiation be just up and down?"

A 1/2-wave perimeter closed loop has a diameter of 0.16 wavelength and at the feedpoint appears as a high-impedance parallel-resonant circuit. Radiation resistance is about 4.5 ohms as determined at the high-current point in the loop opposite the feedpoint. The high feedpoint resistance varies as the smallness of the conductor.

A 20-ft diameter loop has its first resonance at the frequency where its diameter is 0.16 wavelength. If 6.1 meters is 0.16 wavelength, the loop is resonant at 38 meters.

The 20-ft diameter loop at 7.9 MHz (38 meters) has a slight gain in the direction of the high-current point opposite the feedpoint. It also favors the vertical axis of the horizontal loop.

If this 20-foot diameter horizontal loop were used at 160 meters, the current wouldn`t be much different anywhere in the loop. The perimeter is too small in terms of wavelength. The radiation resistance would be very low making conductor loss a large part of the load.

The small phase difference of current around the loop at 160 meters would make the loop omnidirectional in the horizontal plane. Problem is the low efficiency. There is a null in radiation on the axis of a very small loops, so the up and down radiation of such a horizontal loop is further reduced. It would probably be an antenna of last resort.

Best regards, Richard Harrison, KB5WZI

After doing calculations on my Low Band 4 Square vertical arrays to check the field levels sorta nearby in the house I was suprised. There was less to worry about closer to them than I thought. In theory, I could stand maybe a dozen feet from one of the elements key down continuously on CW for a while and not be over the limit. But the game got more serious quickly as the frequency moved up.

I suddenly saw that might not be so good an idea right under a tri-bander mounted on the chimney with the shack in the attic next to the chimney.

Sitting in close proximity to an attic loop obviously has a relationship to how much power you are going to run, one would think. A QRP addict (attic? grin!) would be a brainer! OTOH, running RTTY and and almost always on-the-air bulletin operation on a higher band and snoozing under it for days and days all the time might be a no brainer too!

Use one of the calculations packages out there on the web. I'm not at the station site now, but if you don't find it or something useful in a GOOGLE search or whatever, and nobody else offers, I'll post a way to get at the University of Texas utility which was a free use program for checking this. With a little bit of work you'll get a much better insight into the issue.

Bottom line. From extrapolating what I learned at the fixed site, attic antenna work is probably fine for generalized low power work, surely on 40, 80 and so on. OTOH my comment might generated some 'heated' discusion!

Source record: 132455

I am building a QRP HF amp that will put out 40 watts when driven with 2 watts. Its output power (and power consumption) varies linearly with driver power. Two watts is the max input. It sucks 9 amps at 40 watts. When I am in the woods, I want 10 watts out with 2.5 amp suckage-- to be used when no one hears me on 2-3 watts barefoot.

I have a Ten-Tec 1340 40M CW QRP transceiver. It puts out 3 watts. Gain is not adjustable, except that a resistor can be replaced (with soldering) to make a permanent change in output power. Lowering supply voltage lowers output power a bit, but below 9V, the VFO is unreliable.

I would like to drive the amp with the 1340. My first problem is to get the 1340's power down to 2 watts, so I don't fry the amp. The second problem is to make the power into the amp adjustable down to 0.5 watts so the amp will put out 10 watts and not exhaust my battery pack.

Can I put anything beween the radio and the amp to burn off some wattage? It happens in my feedline when I don't want it to. Will resistors on both legs of the line work? A resistor across the two legs?

Obviously, this will waste some power but it is at most 20% of the combined total and can be tolerated from time to time when I need higher power.

What about a second antenna with its feedline tapped in? Then nothing would be wasted.

Dick,
The lowest angle of radiation depends on the frequency
of use, and the antenna's height above ground, for a
particular frequency, height makes the most difference.
At a height of about 20 feet (average height for a one
story house's attic?), the RF exposure tot he room below
the antenna won't change much no matter what frequency
you use, or what the 'take off' angle is. If you use the
antenna on the HF bands, the RF exposure should be at an
acceptible level. On VHF or UHF, that's a difference
story, depending on power used. This doesn't say anything
about how well the antenna will work for you.

Michael,
A 1/4 wave antenna at about 315 Mhz is close
to 3/4" in length. A 1/2 wave about 1.5" long.
If the frequency of use is higher than 315 Mhz
the antenna would be even shorter. Depending on
how large the transmitter's case, either should
work okay for you. As for the receiver's antenna,
I would think that the length should be about the
same. Height will make more difference than it's
length will. I wouldn't expect much range, no matter
what antenna you used...

if you can permanently change the output power by changing a resistor why
not replace the fixed resistor with a variable one?

if you don't want to modify the rig then check out circuits for attenuators,
for low power and something that probably isn't real critical about
impedance a simple resistor circuit should do it.

Yup. Good plan.

> inspection and preventative maintenance, since nothing will be a permanent

Or not. After the twoers are mounted and vertical, they fill the
gap with morter to seal the gap. I'm sure the morter could be
chipped out and replaced if need be, but it is a very generous layer
stuffed under the tower.

The power company put up some nice new steel towers around here,
using the "two nuts holding the base above the concrete" approach.
One tower in particular, a corner, has a concrete base about 6ft in
diameter. The concrete ends a few inches above ground level. The
tower base (an octagon?) has several bolts on each side. It seems,
IIRC, that four sides (eg N, S, E and W) have five bolts each, while
the sides in between those have only three bolts each. The base of
the tower was kept about 2" above the concrete and (from a vehicle
waiting at the corner) the bolts protrude 1" or so above the nut on
top of the tower base. Pretty impressive construction. The other
towers were somewhat smaller but nearly as impressive.

Within one month after the towers were apparently finished, a crew
came by and mortered in the gaps between the tower bases and the
tops of the concrete. Maybe this stops so many critters from
crawling under the tower and up into the hollow interior?

1323. Passive re-radiate UHF signal?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 18:02:12 UTC
From: Charles McDevitt <Chuck_McDevitt@m-s-n.com>
Message-ID: <ugyM2BFfCHA.1648@cpimsnntpa03>
Source record: 132462

I have a large hill directly between me and a UHF transmitter that I want to receive.
The hill is dead-center in line with the transmitter, and close to where I live,
but tall enough my antenna can't "see" over it.

So, I was thinking, and wondering if this would work:

If I take 2 UHF antennas up on the hill, and point one to the UHF transmitter,
and the other to my house, and then wire the two together, will this do anything useful?

It seems like this would passively re-radiate the UHF signal, and allow me to
see over the hill, but I don't know enough to tell if this can work.

Anyone here know the answer?

Chuck

Minds of persons who don't manufacture kits think alike. I had the
same thought. This is what Ten-Tec said, verbatim:

"this is in the emitter of the driver don't like pots there for rf. "

The same response was given for a pot relocated to a different part of
the box.

Ken,

Since you are building the amp, why not build an attenuator in to it. My guess is that a 22 ohm 1W series resistor, and a 100 ohm 1W shunt resistor (on the amp side) is about right. The 22 ohm resistor would go in place of the wire that connects the input jack to the amp board; the 100 ohm resistor would go from the board end of the 22 ohm resistor to ground. Accurate calculations would be pretty moot, because there is no assurance that the amp has a 50 ohm input impedance. While testing the amp, I would temporarily put a third, less than 100 ohm, resistor across the 100 ohms to keep the power down. Also, for initial tests, keep the key down time to a couple of seconds (nothing to do with the attenuator). If you can't find 1W resistors, use two 1/2 W resistors of twice the value (47 and 220) in parallel.

This is a great antenna for a newbie to build and to model using NEC.
I did that 2weeks ago to get some antenna up for this weekends CQ WW
DX SSB contest. Here are the construction details.
2 6' 3/4" 0.125 thickness Al tubes
2 6' 5/8" 0.125 thickness Al tubes
15' Fiberglass Wind surfing pole
2 2" Stainless Steel Hose clamps
3 3" Stainless Steel Hose clamps
2 5" Stainless Steel Hose clamps.
2 1"x5" Strips of 1/8" thickness Al
1' 1" Sched 40 PVC pipe
8 2" #8 Stainless Steel Machine Screws + washers + nuts
4 2" #8 brass Machine Screws + washers + nuts
Silicone Caulking
450 ohm Ladder line
Tuner

Building procedure:
The holes you will be drilling should be big enough for #8 Machine
screw.
1. Take the 5/8" Tubes and Drill Holes at 36" and 39" from one of the
ends.
Sand the areas around the 36" Hole.

2. Take the 3/4" Tubes and Drill Holes at 2" and 5" from one and a
0.5" from the other end. Sand areas around the 2" and 0.5" sets of
holes.

3. Take the PVC pipe and Drill holes at 5" and 7" from one end. Widen
the hole on one of the sides of the PVC pipe so that the head of the
brass screw will completely go through the hole. Make sure you do not
widen the hole on the other side.

4. Take the 2 metal strips and drill 2 holes 4.25" inches apart along
the centerline of the strip.

5. Take a hacksaw and cut a few 1.4" slits on both ends of the PVC pipe.

Assembly.
1. Take the 3/4" tube and push the end with the hole at the 0.5" into the PVC tube. When the hole shows up on the first 5" hole put a brass screw through the side with the big hole. The head of your brass screw will be directly contacting the Al tubing. Put a washer and a nut and tighten it down. Repeat the proceedure for the other side. Now Slide the 2 2" hose clamps over the PVC pipes. Align the clamp to one end over the slits and tighten using a nut driver. The PCV will compress and grip the AL tubing. Repeate proceedure with the other clamp.

2 Now take the 5/8" Al tubing. Line up the hole at 36" with the hole at 2" on the 3/4" tube and put a brass screw though. Tighten. Put stainless steel screws through the hole at 5" on the 3/4" tube and the hole at 39" on the 5/8". Put the metal strip in and tighten. You should have a T which not going to wiggle or droop. Repeat process at the other end.

3. Take the ladder line and hook the 2 ends to the Brass screws in the PVC pipe.

4. Apply caulk liberaly at all the points that have brass screws.

5. Overlap 3' of the bottom end of the antenna with the Fiberglass pole. Spread out the 3 3" hose clamps in the 3' overlap zone and tighten.

6. You are almost there. Lift the whole asembly and tie the fiberglass pole to a vertical support using the 5" hose clamps.

7. Run into the shack and tune it to the band of interest. 20 15 and 10 work real well.

The first contact for me with this antenna was RZ4FA on 14.225 and he gives me a 5/6 Followed by AA3b on 21.387. The next day was LW9DHR on 28.344. NEC tells me that the radiation resistance on 20 is about 15 ohms, on 15Mtrs it is about 35, on 10 it is about 60.

I used the Al from a Full size 20M beam I used to have. The Fiberglass pole was picked up for free during the Dumpster Day in our community. Hose clamps and screws etc were from Home Depot.

Build and have fun. See you on the Air.

This may indeed be feasible but since all I do is mindlessly snip,
bend and solder I don't know that it won't mess up something else. I
will ask on the BBS for the amp project.

Is there a reason I can't move the attenuator circuit you mention
outboard to an adapter between the radio and amp? Isn't the coax
sheathing of the cable grounded?

BTW, what attentuation factor would the changes you suggest provide?
Is it from 3 watts down to 0.5 watts?

And could pots be used instead of resistors to make the attenuation
variable?

Also, I would need to be able to switch the attenuation in and out.
When I am near my vehicle or in a motel room, I will have the 9 amps I
need for 40 watts.

Huh? A half wave antenna at 315 MHz is about 1.5 feet, not inches.

I believe that small loops are most commonly used as antennas for small transmitters intended to be held in the hand or worn on or near the body.

Howdy.

You may NOT need an "antenna tuner".

If your antenna has an impedance of 50 + j0 Ohms, and if your t-line has a characteristic impedance of 50 Ohms, and if your transmitter expects to see a 50-Ohm impedance (50 + j0), then you will not need an antenna tuner.

I have such an antenna and I do not use an "antenna tuner".

This is said to work. I'm sure that I have seen an article in a cable TV
technical journal (about 20 years ago).
There may be a bit of a snag. If your redirected signal is only about
the same strength as the direct signal, and the two arrive at your
receiving antenna in antiphase, and the effect may be that the resulting
signals is even weaker than when you started. But I reckon it's worth a
try.

If there is no capacitor bypassing the resistor then what they say is
true. The unbypassed resistor is introducing degeneration and
lowering the gain (and distortion). As such, it is an rf component
and needs to have predictable rf characteristics; something that the
pot does not.

On the other hand, if there is a bypass capacitor then the resistor is
affecting only the dc operating point and a pot should be just fine,
as long as it is within the same range as the fixed resistors
permitted.

I'm trying to get a decent setup to receive from APT pictures from
weather satillites on 136mhz on my scanner. Do you know if these VHF
amplifiers made for tv's will boost the signal for receive on rf?

http://www.radioshack.ca/estore/Product.aspx?language=en-CA&product=1501118&category=Amps%
2c+Splitters%2c+Wall+Plates&catalog=RadioShack

136mhz sits right in the middle of the range that this is supposed to
boost. Do you know of anyone that has tried these things for radio
instead of tv?
TV Channels:
AIR 2 55.25 VHF-LO
AIR 3 61.25 VHF-LO
AIR 4 67.25 VHF-LO
AIR 5 77.25 VHF-LO
AIR 6 83.25 VHF-LO

AIR 7 175.25 VHF-HI
AIR 8 181.25 VHF-HI
AIR 9 187.25 VHF-HI
AIR 10 193.25 VHF-HI
AIR 11 199.25 VHF-HI
AIR 12 205.25 VHF-HI
AIR 13 211.25 VHF-HI

Anything like this that I can find for radio is used for transmitting as
well and cost 10 times more. I just need something that will boost the
audio signal so I can get a clearer picture from WXSat.

Actually, if the transmitter expects to see a 50 ohm impedance and sees
anything between 25+j0 and 100+j0, you will usually not need an antenna
tuner. My antenna impedance is almost anything within reason, and my
Z0 is about 400 ohms. Chances are, if you feed your ladder-line fed antenna
at a current maximum point, your transmitter won't complain.

1337. Re: Designing a small antenna for a small keychain

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-25 22:19:36 UTC
From: fractenna@aol.com
Message-ID: <20021025181936.18222.00000396@mb-cv.aol.com>
Source record: 132476

I have had success with a set of designs which does pretty well to optimize the link: read distances of far greater than 100 feet have been attained at this 315 MHz band.

What I can pass along to you is that you must make up for inadequacies in the tag by the reader--and making that smallish and acceptable in form factor is a real challenge. Spent a lot of time on it. Both antennas are fractal.

Perhaps there are other ways to approach the problem; just wanted to let you know its been done successfully to shrink these down to practical sizes.

On the other hand, the read/tag system for gasoline stations was never intended to be a particularly robust system. So I suspect your 'keychain' system is never meant to be read more than 10-13 feet away. In that case, very poor tags work with very good readers. Those readers need not be the somewhat doltish magnetic loops, that are big, directional, and don't do well with metal in the near field of mounting.

Hope this helps.

Hi Harold, As you said, way back when, Art Collins designed an antenna which today looks like the G5RV. It apparently was a multilobed pattern antenna and held a Collins patent. If you get responses to your query offering multi copies, I would be also interested. Keith, VE3JKC

Yes, it will amplify 136 MHz. But its debateable if it would help in your case. The noise figure of the amp needs to be better than the noise figure of the front end of your receiver or it will actually worsen the reception...in this case it would be hard to guess which has the better front end. Plus, since its a broadband amp you could be bothered with intermod from strong local FM and TV stations.

The first area for improvement generally would be the antenna and coax. After you're convinced that you've done your best there, an antenna preamp mounted AT the antenna would be the most helpful. Antenna preamps, even Radio Shack ones, generally have a decent noise figure - much better than the little distribution amp shown. And by having the preamp at the antenna, your feedline *generally* won't be a contributing factor in worsening the signal-to-noise ratio.

Hi Fred.

To the comment above, I would offer that, yes, you do comply
literally with the distinctions you are wishing to make; however, in
the day to day life they are often merged.

One example drawn from the quote above is that there are a myriad
characteristics that could be drafted to formulate an FOM. For Yagis
you mention front-to-back ratio and make a distinction of its choice
as an allusion ("alluded to as..."). THIS is the subjectivity of FOM
because you allowed the caprice of other's subjective attitudes to
force a selection.

FOM is a subjective declaration of what is important to the formulator
of the list (one must necessarily shorten the myriad to a manageable
few). Editing such a list can be extremely subjective through its
covert form of bias in selection. Cost is openly subjective, but Cost
is a far more impartial arbiter of outcome because the biases are no
longer veiled. An FOM from my current customer would never get
designed - too many design issues at cross purposes. However, a risk
analysis will force them to pay for what they want - and they will get
what the pay for. Risk analysis gets things done or abandons the
cost. FOM is an intellectual wet-dream.

All antennas should be checked when installed for SWR. After that you don't need one. You should check the swr every once and awhile just to be sure something has not changed such as the wind breaking off the top of the antenna or the coax comming loose. Good thing about vhf and above is that if you use coax that has about 3 db of loss or more the swr will be seen as under 3:1 in most cases. Most coax falls in this class for 100 feet or more.

I have to admitt that I have several swr meters (actually directional wattmeters) and I almost never check the swr of the antennas I have above 6 meters afiter I install them.

Hi Chip,

I was going to respond in some detail but this would turn into another endless loop. From the early comments in your post, its obvious that if you can't arrive at an optimized design you'll simply blame the FOM. You've tried to set that scenario up nicely.

As for the rest of your "truth in science" comments, I've stated my opinions on fractal antennas quite publicly at the 2001 and 2002 AP Symposium and the 2001 and 2002 Allerton Conference. There were also three recent articles in the IEEE AWPL. Keep your eyes on the next few issues of the Microwave and Optical Technology Letters, the next issue of the IEEE AWPL and upcoming issues of the Transactions and AP Magazine. You'll find the next 6 - 8 months very interesting.

I look forward to your optimized design next month.

Ken,

The values I gave would knock the 3W down to 1W, provided the amp input is 50 ohms. If you want more power, make the 100 ohms bigger. You could build this in the small Radio Shack metal box. They are about 2 inches on a side. Realistically, all you would need to bypass it is to short out the series resistor with a switch. A potentiometer would probably not work, the small "volume control" pots won't take any power, and power pots tend to be expensive and wirewound - ie inductors. I think RS sells resistors in 5 packs. You could use 5 x 470 ohm resistors in parallel for the 100 ohms, and if the ~1W is too low, start clipping out 470 ohm resistors one at a time until you get the power you want. Your amplifier input impedance is liable to be anywhere between 25 and 100 ohms, so you have to experiment.

Hi JJ, the small one turn 'magnetic loops' are fed somewhat
that way, but with a much smaller inside driven loop. If you
are putting up a large wire horz. loop, what is the point, it
will not give you any higher gain unless you are going to
stack the loops and from 40 meters down, you are talking
some pretty tall support masts.

If you are looking for more gain using horz. loops, may I
suggest putting at least 2 loops up that are more than 1 WL
apart and fed with 450 ohm ladderline/300 ohm twinlead.
At the design freq. of 40m. and down these are some
terrific NVIS antennas, especially with a counterpoise
laying on the ground. They also make great multiband
antennas, but they are certainly real estate intensive.

With the above in mind, how about telling us what you
want the horiz. loop / loops to do as far as radiation?
And while you are at it, how much real estate do you
have available?

1348. Calculating NEC or EZNEC models with a MININEC engine

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-26 01:29:42 UTC
From: ac6la@arrl.net
Message-ID: <960228f1.0210251729.20f41d6e@posting.google.com>
Source record: 132487

The latest version of the freeware MultiNEC program has an interface to the "Antenna Model" package by Teri Software (www.antennamodel.com). Antenna Model (A.M.) uses an enhanced and corrected MININEC type engine. As L.B. Cebik pointed out in a recent article, there are certain types of models that cannot be processed accurately by NEC-2 or, to a lesser extent, NEC-4. See "When MININEC is Superior to NEC" at www.cebik.com/amod/amod56.html. And even for models that don't fit this criteria, A.M. offers some pretty impressive graphics capabilities. See, for example, www.qsl.net/ac6la/adhoc/am3d.gif (18 KB).

Being MININEC-based A.M. of course does not support Sommerfeld type ground or "NEC type" (ideal) transmission lines. Except for those restrictions, models in any format that is recognized by MultiNEC (EZNEC, NEC, MMANA, ELNEC, AO, Nec/Wires, A.M., or the Excel-based MultiNEC format itself) may be calculated using any engine that is supported by MultiNEC (EZNEC Standard; EZNEC-M Pro; EZNEC/4 Pro; Nittany NEC-2 [NWPlus and NWPro]; Nittany NEC-4 [GNEC]; public domain NEC-2; or corrected MININEC [A.M.]). You could for example use A.M. to get a "feel" for the 3D radiation pattern but then use EZNEC or NEC to obtain precise impedance and gain figures with the use of Sommerfeld ground, all while building the geometry of the model just once. Or you could use MultiNEC in its more traditional "make multiple runs while automatically changing variables" mode with A.M.

The latest MultiNEC release has several other enhancements, including the ability to read and write 2D radiation plots in OpenPF format. These "plot files" can be exchanged with other programs that use the OpenPF format, including EZNEC and A.M.

For more details on MultiNEC and a free download file see www.qsl.net/ac6la/. MultiNEC requires Excel 97 or later.

73,
Dan AC6LA

You mostly likely need an amplifier at the antenna rather than one
inside near the radio. Placing the amplifier at the antenna will
overcome the loss in the coax cable and the resulting signal-to-noise
degradation.

So you should be looking for "mast-mounted" amplifiers. Any of them
rated for VHF use will work at 136 MHz. Some of them have an
"FM-trap" that is designed to notch the FM broadcast band and this
might have some effect, so switch it out.

Hi, Tam.

OK. I made a diagram and dusted off Kirchoff's Law to see what you
were doing. I am getting a different result, so I am missing
something.

In the unmodified circuit and assuming 50 ohms of impedance in the
amp, for 3 watts dissipated, I get 12 volts across and .25 amps
through the amplifier.

Inserting 22 ohms into one leg of the drive and shunting with 100 ohms
to ground, I compute the new voltage drop across the amplifier to be
9.8 volts. This is only a 20% reduction, whereas you say it should be
a 50% reduction.

Ooops. I see one mistake I made. Recomputing, I find around .22 amps
flowing through the 22 ohm resistor and a voltage drop across it of
4.8 volts -- presenting 7.2 volts to the amplifier, for a reduction of
40%. Is this correct?

I think I have it. If I want an 80% reduction and assuming the amp
has 50 ohm impedance, I compute that the shunt would be 12.5 ohms and
the series resistor would be 40 ohms. Is this in the ball park?

This seems very straightforward. I wonder why Ten-Tec didn't suggest
it?

I think I can use a DPDT switch that would give me two alternate
arrangements: 30% off and 80% off. That would be entirely
satisfactory.

Source record: 132497

I encountered a van with an unusual pair of antennas on its roof, and I am curious as to what its use might be.

The van had two identical T-shaped antennas, one at the front of the roof, and one at the rear of the roof.

The antennas were two or three feet tall, with the horizontal element at the top of the T spanning the full width of the van.

The antennas were 1" to 1 1/2" thick. I assume that that is either for rigidity or for high current capacity.

The middle of the vertical element of each antenna is bent into a few turns of open coil.

Any thoughts regarding what it might be?

I needed an swr meter to adjust my dual bander mobil whip when first setting it up. After the length of the antenna was adjusted, the meter was no longer needed. If you rig doesn't have a meter built in, and you don't want to buy one, maybe you can borrow one for the initial setup on your antenna.

You will need high gain antennas.

It works at about 10x the frequency with microwave dishes. A "passive repeater" is sometimes made of back-to-back dishes connected with a short length of waveguide. "Billboards are more popular for their higher efficiency.

Each microwave dish is only about 55% efficient and the waveguide adds more loss.

For UHF, the yagis, rhombics, etc. are less eficient than dishes. Dishes and bilboards are likely out of the question due to size. The only way to determine the viability of back-to-back UHF antennas in the particular situation without path and signal strength information is to give it a try.

Ken, I did 100 ohms in parallel with 50 gives (50 x 100)/150 =33 ohms. Now there is a voltage divider of 22 ohms in series with 33, which gives V(new)=V(old)x 33/(33+22))= .6 V(old). But, you square that for power; so, the new power=3W x .6 x .6 = 1.08W. Notice that the transmitter sees 22 ohms in series with 33, or 55 ohms. This is pretty good. Now if the input impedance of the amp is other than 50 ohms, like 100, the numbers will be different. That is why you need to experiment.

Well, I live in a neighborhood where no antennas are allowed.... So not to give up my hobby, I devised a vertical for all bands that looks like a flag pole (e.g. has flags at the top). The antenna, itself, is a Shakespeare 222 that I purchased Mil. surplus (came off a navy frigate)... it's 35 feet tall, handles 10kW, has a flanged base for mounting in concrete, a feed point about 2 feet up from the base. I mounted it with a copper plate under it, and put down 240 radials with a radial burying device I built (and now market commercially... see them at Dayton) for my lawn tractor. The antenna is fed with a Mil. antenna tuner (Harris CU-2310)... and the results are simply astounding. I consistently get better signal reports than local guys with "bigger" installations in pileups (we could have a big discussion here about modes of wave travel, but the bottom like is how you do in pileups... no matter what antenna you use). If elevated, 4-8 radials would suffice due to reduced ground losses. I had a dipole up 60 feet, and the vertical beats the pants off it.

Pictures on request! You won't believe it!

As a result of reading the posts here I'm finally getting a grip on
ground losses as applied to a vertical antenna installation. I had
always been under the misconception that a nice piece of earth provided
a better ground plane than say 3 or 4 elevated radials.
With that new piece of info in mind, another question comes up.
I live in a house on a small crowded lot. The biggest open space would
be the roof itself. Typical hurricane proof construction, flat concrete
roof with plenty of steel inside.
So how does this rate as far as ground losses? Would I be better off
laying radials directly on the roof or going to an elevated scheme?
Thanks,
Bill WX4A/KP4

Ground losses appear as a series resistance so a feedpoint impedance
measurement can give you an approximate idea of what is going on.
The feedpoint impedance of a 1/4WL vertical is about 35 ohms over
perfect ground. The feedpoint impedance goes up as ground losses
increase. You can get a *rough* estimate of the ground losses by
measuring the feedpoint impedance. It will (at least should) decrease
as you add radials.

Richard,

We agree in principle. But I surely won't agree that "FOM is an
intellectual wet dream" and hasten to add "if it's being used
appropriately". If the term is misused, that's a different matter. I

suggest using the term "FOM" for objective measures.

I'm afraid we're dealing with some "baggage" regarding what is and what is not an FOM.
I do know that people make up their own. Some of these are perfectly objective. Some... So I agree that in real life they can be merged. But I don't recommend it. I especially don't recommend it if one is dealing with how to evaluate designs. Thus my original post.

And, distinctly and separately, I do know that people use the term FOM when they mean something else.
That's why I gave the examples of an FOM and a cost function or objective function - to show that they are different things.

Just to be clear, I was using "cost function" or "objective function" as a set of optimization constraints, weights, parameters...etc. $$ cost can certainly be part of a design - it should be! But that's not what "cost function" referred to directly.

Also, when I say "optimization" I'm referring to something like an algorithmic procedure (which could include a human in the loop to adjust algorithm properties like step size, reset starting points, etc.) that specifically addresses an objective function.

It may be that such an optimization method can reach an acceptable design without human intervention. However, the criteria for such an optimization should not be called a Figure of Merit.

If I start with either an "optimization criteria", "cost function" or "objective function" and if I have an algorithm that is guaranteed to find a global optimum, that doesn't mean that there isn't a better design. What it means is that there is no better design that maximizes (or minimizes) the objective function subject to the same constraints.

So, this could lead to a trick challenge:
"give me a complete objective function and I guarantee that this or that algorithm will find a solution that's unbeatable".
Well, if that's a guaranteed result, of course!
However, that doesn't mean the specific design arrived at in this manner is "better" than another if different constraints or conditions are used.
That's where the subjectivity comes in. The constraints and conditions aren't an FOM.

I will give another example:

I want to design an array with minimum beamwidth and minimum sidelobe levels and the size of the array is fixed. That's the objective function. We note that minimum beamwidth and minimum sidelobe levels are competing requirements. So, we clarify the requirement so that 20 degree beamwidth is the maximum allowed and -20db sidelobes are the maximum allowed and that narrow beamwidth is more important than low sidelobes. Now we have the design criteria we're going to work with in this case - there could be other parameters.... The resulting design determines an array taper or weighting

function that results in 10 degree beamwidth and -20 dB sidelobes which could be formed into a Figure of Merit of sidelobe level to beamwidth ratio |SL|/BW.

Note that we didn't say that we wanted to maximize this FOM in the design - although we could have added it to the mix - it's simply a measure that tells you something about the design once it's done. In my experience, adding this particular FOM to the mix of optimization criteria would have made the criteria somewhat convolved because we are already treating both sidelobe level and beamwidth anyway.

I didn't follow:

">THIS is the subjectivity of FOM
> because you allowed the caprice of other's subjective attitudes to
> force a selection."

I'd rather not deal with attitudes here. I'm not suggesting any sort of "forcing". The FOMs that I suggest be OK are completely objective in their definition. That's not to say that assigning a value to, and including, one of these FOMs as part of the mix in a design goal mix doesn't involve a subjective set of decisions.

Bottom line: Don't use the term FOM when you mean "design criteria" or "objective function" or.... that's the recommendation. Of course, folks will do whatever they feel is best for their situation. My objective in starting the thread was to suggest something that might be useful - if one chooses to adopt it.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.swap,rec.radio.scanner

Do you have a need for a high-quality SMA-to-BNC antenna adapter that
is custom made to fit and protect your H.T. or scanner radio?

Adapter allows you to:
Quickly change antennas to base, mobile or different style use.
Use the more popular and wider selection available of BNC antennas.
Prevent chassis connector wear or from coming loose due to antenna
changes.

Adapter features:
Gold plated contacts with a teflon insulator.
A low profile design with a rubber covering for a factory antenna look.
The rubber base seals to the top of the radio with no spacers needed
for moisture and dirt protection.
The base also provides an excellent support for any length of antenna
or application.
No need to remove adapter once installed to make a quick and safe
antenna change.

Sizes to fit radio models:
Yaesu: VX-5, VX-1, FT-50-R, VX-10, VX-150, VX-110, VXA-100, VXA-120
Icom: IC-T90, IC-T8A, IC-T81A, IC-Q7A, IC-R2
Kenwood: TH-D7, TH-G71, TH-F6A, TH-F7A
Alinco: DJ-V5, DJ-X3, DJ-S40
Standard: C508A, C510A
Radio Shack: HTX-420, HTX-400, HTX-245, HTX-200
Aor: AR-16

Previewed in the May 2000 Issue of CQ Magazine, and the Nov. 2000
Issue of QST Magazine.

$11.95 + $1.50 S+H(One to unlimited)

This is true only over the lower end of those same, several octaves.

>
>For best performance from 0.1 MHz to 2.6 GHz requires several antennas.
>To listen to space coms may require several antennas, and reception from
>nearly directly overhead where the dscone has a null.

Hi Richard,

I have a model, a 16 spoke style (not solid sheet) discone that just manages to exhibit the hallmark characteristics found in text books. Of particular note is that at the low end of its service range (40M) where the feed point is at an elevation of 40 feet (the lower spokes's tips are 10 feet above ground) it has a sharp radiation lobe peaked at 20 degrees. (EZNEC reports -1dBi allowing for losses and real ground).

When I tune up to 10M, it matches as it should, and it shows about 6 dB more gain - with a sharp lobe at 60 degrees. That former 20 degree lobe is now suppressed 10dB below this peak.

With a radical shift to 2M, it is stumbling out of match (possibly due to a lack of segments - the model running at 497), but throwing caution to the winds, I press on and find EZNEC reports roughly the same peak gain, but now at 85 degrees, and that former 20 degree lobe still buried at -10dBrePeak.

Well, to an avid 40M/10M/2M user, this is mixed news; as the adage goes, one man's meat is another man's poison: translate the antenna size to your bands of choice. Our original poster, John, could observe some cheap gain in using tall verticals to aim at the stars. With a discone it could be very useful to turn its deficit (that high lobe at the upper end of the match range) into an asset (space comms). Hopefully, the lower end of the match (with a view more toward the horizon) is a band you already want to focus on.

Just a follow-up...
If you do get signs of cancellation, you can always set the 'transmit'
antenna to the opposite polarisation (ie probably vertical in your case,
with the antenna on your house also vertical).

In the UK, there are a few very isolated places where the local
community has, with official sanction, installed a 'self-help' on-
channel relay of the UHF TV signals. This is what you propose, but with

an amplifier between the antennas. This is obviously more effective than the passive arrangement, but you have to provide power. You also must ensure that there is sufficient isolation between the antennas (I reckon that this would need to be at least the gain of the amplifier plus 20dB) - and cross-polarisation also helps here.

Ian.

Oh, did he say that he was doing all his communicating at the azimuth and elevation angles where each antenna's gain was maximum? I missed that part. Must have been tricky to do. . .

Thank you, Tam.

Can you please tell me one more thing? The kit project manager
responded to me and showed me how to modify the amp to get whatever
attenuation I want by changing resistors in the amp. However, this
does not give me the flexibility I want to change the attenuation in
the field, so I will be making an attenuation box with a switch.

His attenuation circuit has two shunt resistors -- one before and one
after the series resistor. Do you know why it is done that way? See
R2, R3 and R4 at:

**NOW AVAILABLE **
Program BOTLOAD2.exe"

An improved version of "Botload" which is now no longer available. This simple program calculates base feedpoint impedance, R+jX, of any vertical antenna height and diameter. Also value of inductive or capacitive bottom loading component. Also, for given length and diameter of loading coil, the number of turns, winding pitch and wire-gauge.

Vary antenna height from keyboard to find heights at which feedpoint resistance matches 50 or 75-ohm coaxial feedlines. Or any other particular Zo. Metric and Imperial dimensions displayed.

Download in a few seconds. Run immediately.

Thanks for the reply Cecil, but my question was regarding the actual
effect of the roof and I guess that wasn't clear. I don't have an
antenna erected yet and am trying to get some advice about which would
be the best starting point - elevated with radials or radials laid on
the roof. Then I can proceed as you suggest.

Thanks again,
Bill

Ken, if you are building the HFPacker amp, it already has an attenuator and they talk about how to adjust it for different inputs.

The original amp would deliver around 35 watts with 1 watt in. They put in an attenuator for 2 watts. Later they changed it to 2.5 watts because apparently the FT-817 can't get to 2. But if you read through the builder's notes, they talk about it.

Jack K8XX makes a good point about reducing the drive back in the exciter, since this will result in lower battery use. But it does sound like that might be a little on the challenging side.

"Beats the pants off it" with no stated conditions means to me that
it beats the dipole at all distances in all directions. I simply do
not believe that.

Ken,
I looked at the schematic. That certainly would work. Using 3 resistors is the preferred way to build an attenuator because it gives better control of impedance. In line with Jack's suggestion on saving power, you would save even more if you could raise the efficiency of the amplifier, rather than the 2W transmitter. I assume you are using this for CW. You might ask the amp people if the CW efficiency gets better at 0 bias, that is , with VR1 turned all the way down The gain will go down, but you don't care about that. . Ignore this if you are doing SSB. Another thing to consider. Linear amplifier does not mean that the output power changes linearly with input power, just that the distortion is second order, which gets canceled out in the output transformer and filter. The following is for a Mirage B310G 100 W amp. I have one, and it is linear, but not to gain. I use this at 8 W SSB in. My unit is not this bad, but this is what they claim:
Pin Pout
1/4 25
1/2 50
1 75
2 95
4 100
8 100
What this means is that you migt have to reduce the input power more than you think. Or did they give you a table of Pout versus Pin. I don't remember if that was in this thread. Hope you get it to do what you want.

Point is that nobody can predict the *exact* characteristics
of your roof so "cut and try" will gain you much more information
that all the personal opinions that you might elicit from this
newsgroup. As NIKE says, "Just do it!"

Source record: 132530

Linear should mean that doubling the input power will double the output.
The output should follow the input in a linear maner. Anything else will
create distortion and more likely make for a broad signal. FM will not be
distorted but the ssb signal will. Either one will make for a broad signal
and maybe more harmonics.

As vhf is not usually too well used most of the time the bad signals are not
reported as much as they would on the lower bands. You can usually tell if
someone is using a transistor amp and overdriving it on VHF.

Elevating radials above the ground reduces loss because it reduces the current in the ground, and ground has relatively high resistance. The metal in your roof shouldn't have appreciable resistance at RF, so there probably wouldn't be any advantage to elevating the radials above it.

True. But if I needed to conserve power, I would go out barefoot at 3
watts. If I am using the amp in the field, I have some power to spare
and wasting 2.5 watts of the three -- when the amp is sucking 10 amps
-- is not unbearable.

I expect that my next radio (DSW-II?) will have an effiicient
adjustable gain. That would adress the problem.

Ralph,

Even order distortion will NOT cause splatter. That is because these products will be 2X or more of the signal frequency. Look at P(o) vs P(in) specs for "linear" RF power transistors. The rated power will be beyond the point where the curve becomes nonlinear. You can still have third order products 30 DB down even though it looks like you are operating in the nonlinear region. I think you WOULD get compression of an SSB signal. So, if you were using a 100W transistor as a driver in a TV transmitter, you would have to derate it.

BTW The amp that Ken is building uses IRF510 transistors. These are DC/DC converter transistors, and there is no data in the Motorola book on their use as amplifiers; doesn't mean they won't work - remember the sweep tubes (maybe not)!

Source record: 132535

You need three resistors if you want to simultaneously specify the resistance looking at the attenuator from the input side, the resistance seen from the output side, and the attenuation. If you'll settle for control of only two out of these three, you can get by with two resistors (an L section). And if you'll settle for only one, you can do it with one resistor (series or shunt). These all assume that the source and load are purely resistive. If there's reactance involved, the problem increases in complexity, and the attenuator has to include capacitors and/or inductors if you want to satisfy impedance requirements.

So you can have a three resistor attenuator that looks like a 50 ohm load to the driving device, like a 50 ohm source to the driven device, and with the attenuation you want. There are two ways to connect the three resistors, pi and tee. For any pi network, you can design a tee network with exactly the same impedance and attenuation characteristics -- if you put the two into black boxes you wouldn't be able to tell which you had. So you can choose which one to use on the basis of convenience in resistor values and dissipation. (The total dissipation will be the same for two equivalent networks, but it'll be distributed differently among the resistors.) If you want to make it adjustable, one choice might allow more adjustment than the other with a single variable resistor before the mismatch becomes intolerable. If you don't want to spend a lot of time playing with equations, simply build a pi attenuator with an adjustable series resistor and a tee with an adjustable shunt resistor and see if either will give you the attenuation range you need without unduly disturbing the transmitter or amplifier (or cooking the variable resistor).

Pi sections are usually chosen for switchable attenuators since the topology lends itself well to mounting on slide switch terminals. Pi sections are also convenient from an inter-section shielding standpoint -- the series resistor can be passed through the shield wall, with one shunt resistor on each side. This provides fairly good isolation of the input and output currents. But from a circuit standpoint, a tee section does exactly the same thing.

Group:

I sent Bill some other details, but it dawned on me that I need to share the following. Concrete plus rebars when immersed in a RF field is an intermodulation distortion generator. For average receiving, it probably would be unnoticed, but any transmit power, or even low transmit power while trying to receive weak signals is a bummer. The group I work with has measured several cases of concrete IMD problems at DF sites, and one involved a VHF transmitter with the antenna too close to the roof which caused the HF noise floor to rise significantly whenever it was keyed. If it were me, I would string a number of radials above the cement roof to minimize the currents in the roof before transmitting in the configuration that Bill describes.

==========

On the other hand, with high resistance soil such as dry rock and desert
sand which have the properties of insulators, the loss in the ground will
again be very low.

So what value of soil resistivity results in maximum loss ?

Roy,
Right you are, but the transmitter wants to see 50 ohms. What its output impedance is, nobody knows.

The tubing cutter is absolutely great for that. And I use
it to strip the jacket, too. Makes removing the jacket a
pleasure instead of a chore! You don't have to use the
kind for small spaces - the bigger ones work, too.

>
> Jim
> N8EE

Three possibilities come to mind:
1. Contact Ford and ask.
2. Make a capacitor of two 2" or so plates and stick them on
the transparent glass with masking tape, with a short lead from
the inside plate to the car body as close as possible to where
you'll mount the antenna. Measure the capacitance. Now, move
the capacitor to the tinted part and measure again. Should be
about the same if the glass does not have a metallic tint.
Unfortunately, Fords are known to use metallic tint, if what I
have heard is true.
3. Go to a mobile phone installer and ask them about thru
glass antennas on a Taurus.

OK - well, this will probably change things a bit: I got the 433.92MHz chips. Hopefully that makes things easier... I found out about the chips from someone with the screenname "grog" from sci.electronics.components. He actually told me about the TLP-434 and RLP-434 - but when I called Laipac to order - they only had the new and improved TLP-434A and RLP-434A. They were still just incredibly cheap though. (like I think about $4 each!) So, what affect would this frequency have on things? Thanks!

>give it a try.

A guy I know did an installation like this on one of the U.S. Virgin Islands. His dad had a long-term mooring at a marina located on one side of the island, and the only TV station in the area was located on the far side of the island (or on the next island over). The direct line of sight was blocked by the island peak, and signal reception was terrible.

He hooked up a couple of "deep fringe" TV antennas back-to-back on one of the island ridges, aimed one at the transmitter and the other down at the marina.

It worked, well enough to give a viewable picture.

So, I'd say it's worth a try. A couple of homebrew Yagi antennas cut for the UHF repeater frequency shouldn't be hard or expensive to build.

Well, it works both ways. The transmitter would like to see 50 ohms, and the amplifier would also probably like to see a 50 ohm source, so without any other information it's probably best to design for 50 ohms at both ends. Of course, if the impedance at one end of the attenuator isn't what you design for, then the impedance looking into the other end won't be what you expect. But the more attenuation you have, the less the deviation will be. Also, if the impedance at either end isn't what you design for, the attenuation won't be what you expect either. But it would certainly be close enough for the application at hand.

An ongoing controversy about the nature of a conjugate match has spurred a number of people to measure the output impedances of a number of amplifiers using various methods. It seems that they mostly actually do look a lot like 50 ohms when adjusted for rated output. This certainly isn't a requirement, though, and there might well be plenty of transmitters out there that don't.

Bill,

You've received many good post already.. but here is one from a
practical point, because I was in a very similar situation as you ,
Cement roof full of rebar and screen .. Mine had a metal vent pipe
comeing up through it which was tied to the metal mesh in the
concreate. I mount my 14AvQ on that , and it worked great on 40 and
15 on 20 and 10 had to readjust the traps slightly to get good swr .

over all the antenna system worked alot of DX but I was only 400 feet
or so from the Ocean at that time also.

I would lay any radial right on the roof first. though you may not
need them .. Happy Hamming,
73 Dave

The following material, authored by Nathan Cohen, has been extracted from usenet:

==========

C____, this is the last post in which I will allow you to be off topic. You have been asked to engage in a debate. I respectfully request that you consider it, weigh the options, and get back to the NG.

Thank You,

Chip N1IR

If there is a tangible basis for your (bogus) assertions then there are a number of avenues you have to stop this (bogus allegation of) " crass commercialism"; this (bogus allegation of) "flim flam", and so on. For example: WHEN I make my 10M runs, I make announcements about the antenna and give the WEB URL and point out its --ham page-- pointer where the antenna is described. I am quite specific about this. Just like I am here. It seems to me that IF you are CORRECT, it would be very easy for you to seek revocation of my ham license for commercial intent and broadcast. I thus invite you to monitor and record my DX sessions, which are usually conducted on weekends in the mid morning and are very easy to find on the band. Lots of US stations tune in just for the fun of listening. I know this because I get interrupted when a semi-rare station calls and someone stateside asks me if they can work it (I say yes.) Tom orrow is a good time to listen--assuming the band is open. I am likely to be on about 1200 UTC or later on 28500-28510. Given your convictions on this matter, you have a moral obligation to pursue them. Your continued silliness of posting in response to my legitimate dissemination about fractal antennas for hams only paints a black picture for radio amateurs in general. Stop this harrassment and save our great hobby.

73

Chip N1IR

Open door, receive summons, go to court, disappear from the internet. Is that your fate this year Mr. R____? That looks what your goal is. As for me, five years of your harrassment is five years too much. Pass that on to your pals too.

Nathan Cohen

I have been asked by many, including G_______, for more HF designs. I am heartened by the positive response, and when I have some time in

the late Spring I will oblige. Note that I am also about half way through another paper for 73 Magazine on just that topic. Also, keep in mind that I do not respond to technical questions on fractal antennas on this NG due to slander, harassment, and death threats received inthe past. I do, when I have time, respond on the fractal antenna reflector on onelist.com.

73 to All,

Chip N1IR

"It has been brought to my attention that an illegal and bogus use of my screenname has been employed here to falsely represent a public message as being written and sent by me. Under recommendation of my attorney, I am taking this sole opportunity to make public notice regarding this: This is a public notification that any and all claimed USENET messages after January 5, 2001, that bear the signature of Chip N1IR, Nathan Cohen, or chipn1ir@aol.com, are false and bogus. Fractenna@aol.com continues to be used by several individuals including myself. This is a legal and long standing use by those affiliated with Fractal Antenna Systems,Inc. However, I do not use this screenname on USENET. I do not participate in USENET. I understand that Phil, N1ZKT, is doing so and he is welcome under the premise so given. Under the recommendation of my attorney, I have not been involved in any USENET activities since 5 January 2001, so that action against certain individuals may proceed. My superiors at my home institution have been apprised of the situation in January. I have not participated in USENET since the January date. Nor do I intend to. Below is the bogus post. It is not an AOL post.It appears to be a routed post through looksmart. That individual must have used either bogus routing or obtained an account which emulates an AOL screenname.It is not me or anyone I know of. I wish my friends well on USENET and remind then that I may be reached by e-mail for friendly chats, or through the various moderated antenna lists on yahoogroups.

Nathan 'Chip' Cohen

N1IR

617-489-6952 "

Mr. P.O. B_______--

There is "no problem with Chip". This is a public notice that you are to stop all such harassing public posts. This is also to inform you that you are requested to discontinue any contact with me whatsoever, starting now.

Nathan Cohen, Ph.D.

Again, you blame an inane behavior of someone olse upon ME. That is a uniquely bizarre protocol found in this NG. I didn't start this thread and certainly have made NO comments which fall in your category.

Bill A_____ is your man. As for Phil, I am NOT Phil. If you are upset with him then address him directly. He can handle himself. You would at least expect Bill, a retired person, to have the time to find the answer to such an obvious question, before attempting to publicly humiliate someone trying to earn a living, and better himself. Especially when that someone is here to help others as enjoyment; a meaningful diversion from otherthings more tangible and burdensome. Life is tough guys; no need to make it tougher than needed. It's a very disturbing attribute found on this NG.

Nathan Cohen, Ph.D.

N1IR

Under advice from my attorney, I will not react to your new comments. Your continued statements place you in the situation discussed off line. It is up to you to seek out an attoprney's counsel on the matter. I remind you that statements such as "alleged PhD", and so on are deliberate efforts to publicly libel. I will repeat a general statement: Malicious libel is NOT acceptable. It can--AND WILL-- lead to litigation. FYI Mr. O'N___ and I are NOT presently, or planning for, litigation against each other. We resolved our differences reasonably. Furthermore, I have publicly asked for the matter to be dropped. Your continued, unwelcome statements go against my wishes.

Nathan Cohen, Ph.D.

I am passing this onto this newsgroup as at least two offendors use this forum to get traffic to websites which have the copyright violations.

---

16 August 2001

Fractal Antenna Systems,Inc. has received and is reviewing requests fo permission to use one or many of its copyrighted graphics, pictures, and/or files subject to its recent 15 August 2001 deadline and guidelines. As of this date those who who have not requested permission to use said copyright materials as per above are considered intentional violators. The firm has initiated efforts to demand removal of said material(s). If said material(s) is(are) not removed immediately upon notice then the firm will seek legal means to stop the violators and recover treble damages; cost of legal fees; and court expenses as applicable, among other costs accrued. Any questions should be sent from representative counsel by registered mail to:

ATTN: COPYRIGHT VIOLATIONS
Fractal Antenna Systems,Inc.
2 Ledgewood Place
Belmont MA 02478"

Thanks and 73

Phil

de N1ZKT

QST--

Messages about patents on antennas have been a common and accepted topic of discussion on this newsgroup. I have forwarded the following relative to this. " Fractal Antenna Systems, Inc., is seeking any extant evidence of infringement of its patents on fractal element technology. The firm designs and sells antennas based on fractal patterns, especially fractal elements. It holds an exclusive set of US patents on said designs and has many other U.S. and foreign pending patents. The firm seeks possible information on evidence of infringement of its patented technology. It has actively sought out such evidence and has taken successful actions to stop said infringement. The firm is offering $1000 reward(s) to those who can present compelling evidence of products in the US market which incorporate its technology from unauthorized OEM's. If such evidence is found and presented, the first case of an example by a specific unathorized OEM will result in said reward to the individual presenting that example. Such individual will be asked to provide an affidavit and additional materials as requested by the firm's counsel. Please send any additional queries in writing to:

ATTN: Infringement
Corporate Headquarters
Fractal Antenna Systems, Inc.
2 Ledgwood Place
Belmont MA 02478"

Thought I'd pass this on.

73

Phil

de N1ZKT

Mr. M_______--

Our attorney did indeed provide that advice; understands and advised me on fair use; defined for me when a quote is fair use and not fair use. My statement then, as now, is based on his counsel. If your incorrect statements lure others into illegal activities, then you are on public record as being informed that you run the risks associated with them. I note a huge number of times you have been profoundly incorrect--always veering on the side of the unlikely; the illegal; the deceptive. The most absurd one to date was your assessment (during my friendly phone conversation) that the 10M fractal quad Yagi was a fake--because you couldn't see the wire in the photos (everyone else

can), and radio shack ground wire couldn't be bent to hold a shape. According top you, any attempt to do this would produce a drooping mess in minutes. Yet the antenna exists, is well used, and has been up for 13 months. Furthermore it has survived an F1 tornado; various ice storms; and the pinching-velcro effect of pesky oaks (when being raised/lowered). This antenna is a survivor, is what is stated, and should be an inspiration for hams to try it and experiment. If that disagrees with you then too bad. The 10M FQY can be seen on the ham page of :

http://www.fractenna.com

The world is not a big conspiracy meant to test your gullibility Mr. M_______. If it was, I sure wouldn't want to be around it.

Chip N1IR

Sir:

You continue, even in this response, to make accusations with intent to slander and defame. For example: "...chance to prove that for once in your life, you are telling the truth." Your assertion that I have spent a lifetime of lies is extraordinary . And of course absurd in its prevarication. It is also one of many statements you have made which are false, but have been publicly made with--intent-- to slander and or defame me.

I want you to review this and other posts with your daughter. If, indeed, she is an attorney, and represents you, IS NAMED 'D___' as you say, I want you to have her call me at :

617-489-8824.

I will then arrange a meeting in Boston between my counsel and her with the intent of an out of court settlement dealing with your trespasses. This will be the last contact I will publicly have with you, whether you are

'L_____' or actually someone else.

Nathan 'Chip' Cohen N1IR

Again, your comments do not seem to indicate a knowledge of lawsuit law. Mine is rudimentary but under the advice of counsel. If yours was under legal counsel, it certainly would not suggest that the party you claim to be suing, had so prejudiced his case that legal representation was not possible. That is exactly what you have just said--twice. Your insinuation is that the party you are suing should not be represented by the legal system. One must further remember that you have clearly stated that your intent for said suit is to bring financial ruin upon me; not as a settlement against alleged grievance, but purely to destroy me financually. In other words, that was ALWAYS your intent, and any 'grievance' is just a ruse for that plan. I presume this will now be run past a judge.

Cordially,

NC

Again,I must apologize to my colleagues for the harassment by an individual on this NG. My attorney had advised me to publicly request that he stop any form of contact with me, which I did. Yet, in the last few weeks, he has taken every single thread in which I have posted-- and addressed me personally, and always either/or portraying my statements inaccurately, so as to make me look foolish and mocked, and/or personally attacking me with abuse. There is, at this moment, nothing I can do about it. The case I have made will take time to bring to the judge's attention and , by definition, invokes the legal system in another state. I do feel that the case for harassment is overwhelming at this point, and I will now bring the problem to the attention of his ISP. My comments regarding this thread are accurate , and in particular, represent the present experience of colleagues who are professionals at cell tower siting and installation, especially in urban areas. I am obligated to defer to their greater knowledge in this area, which I have done. I would like to make one question clear, however. If, as this individual claims, I have made foolish and incompetent statements 3 years ago on cell tower heights, then why has he not re-posted the thread? Again, I am sorry that every time I get involved in a discussion I am mocked and abused, but please understand that I have done all I can to discourage this behavior, and suggest that you personally ask this individual to end his harassment.

Thank you.

73,

Chip N1IR

It would appear that you believe that the only acceptable solution is for me to not have the right to enjoy myself in this public forum, and that I am responsible for said abuse--by others. Thus you are holding me responsible for the actions of others, and removing my right of free speech, and my own reasonable and honest contributions to this group. Is that the gist of it? If so, can you think of any compelling reason why such an attitude should not extend to every segment of my life? In other words, would you say that I should not talk; write; or express any human action, because in doing so there are those who will counter with abuse--even though I have not done so? What, exactly, is your objective sir?

Nathan Cohen, Ph.D.

I can see that Mr. R____ is under substantial pressure. But I am a reasonable person. IF MR.R____ **STOPS** his CONSTANT PERSONAL ATTACKS AGAINST ME then I will not press charges and I will drop my suit. I couldn't care LESS what R____ discusses--usually inaccurately--in technical discussion. I couldn't care LESS what you say about fractal antenna, or genetic algorithms, or the length of a side of an antenna. Why SHOULD I care? BUT THE HARASSMENT MUST STOP. IT MUST STOP. You

have NO RIGHT to put my family through a constant and unabated HELL promulgated on a PUBLIC and GLOBAL SCALE.. YOU HAVE NO RIGHT to make my family uncomfortable when I try to talk to hams. YOU HAVE NO RIGHT to spread malicious and intentionally wrong information about Fractal Antenna Systems, Inc (do you remember when you claimed that the company had been dropped from incoporation last year? Do you have any idea what that did? I lost 4 new accounts because of that LIE!!) DID YOU HAVE ANY RIGHT to trouble my SICK and DYING father with your nonsense? You bet he read this NG! A week before he died, how do you think he felt with your little conversation with R___?? Doesn't a dying man deserve some peace?? EVERYONE IS SICK of your HARASSMENT! You are the key to stopping it. That much is clear. IF YOU STOP YOUR PERSONAL ATTACKS this will instantly be a differentNG. R___ is right: he is worried about some serious issue coming to a head. That is correct. EITHER you STOP. Now. OR the NG continues the way it is; gets worse AND I press charges and complete my civil lawsuit.No bluff T__. Act sane and do the right thing.

Nathan Cohen, Ph.D.

Thank you for your comments B___t. There is nothing in the above post--which you either misunderstand or misquote-- which says that this individual named 'L____' has threatened me. To date, I have not seen any comments from 'L____' which I feel indicate intent to harm. I have made it very clear what 'L____' has done. You, yourself, can freely discover this by doing a power search on dejanews under the keywords fractenna and L____. This will reveal a long-term harassment by 'L____' for which I neither provoked nor encouraged such response. His behavior of late has pushed the issue over the edge. I will take whatever legal measures exist to assure that the harassment and threats, posed by handful of individuals (against me) do not continue. That includes, but is not limited to, lawsuits if and when that decision is made. It should be noted that a grotesque assertion that I, myself, intend others harm or harassment are unfounded, and inaccurate. I would just like these individuals to stop their chronic behavior and I have no interest in devoting any time thinking about them--beyond the time it takes to get them to stop-- through legal means. Matters of litigation, or resolutions outside of court, are not issues for which your opinion can have much relevance to me.
It would be instructive to note the lack of posts (involving me) from some individuals in the last few days. It is probably a good speculation that these lack of posts (involving me) will continue to be absent. That will make for a far more instructive, sane, and useful NG. I presume, you, as I, look forward to that.

Best 73,

Chip N1IR

I assure you that I am not a pseudoscientist. If you would like a nice summary of my scientific work, in context, may I suggest seeing the piece in July 1999 Scientific American. At present, C______ R____,

W8__, is in the process of being sued by me. This has nothing to do with science or objective or subjective critique. It has to do with his harassment and libel and personal attacks. Litigation has been my option of last resort; it is only his obsession with libelous statements--for example, even today he asks' how many lives I have ruined as a professor'-- which has led to this. Mr. R____ has a checkered past . For example, his harassment of R___ M_______ is well-known to the ham community. There are other things he has done which will come to light. I hope this clarifies the issue for you.

With Best Regards,

Chip N1IR

It really is a jaded, mixed up, perverted world you guys see. I must admit, that in your company, I DO feel like an oddball-- a special kind of 'mental illness' where people are starightforward; friendly;helpful; and don't attempt to make personal attacks. Sort of like Erewhon I guess.. Any more Friday Night Specials? I'd like to play magic tR___s with my son:-)

73,

Chip N1IR

Hey there R___

Why is it that when you make follow ups on my posts you send it to Chip? Don't you GET IT? MY moxxon info came for Cebik's web page. If YOU have something else up that's 0.75 by 1 quad sizes then that's a LOT bigger than the 0.57 by 0.63 quad sizes of the 10M FQY. Your moxxon wouldn't even turn in Chip's tower and it would hit two trees in the process. I don't know what makes you think you can come off throwing pot shots and pretending you know what you're saying here and on other posts directed at Chip me, fractals, and so on. The demonstrated FACT is that your moxxon won't work in this form factor and people can't put it up with the same restrictions as the 10M FQY. Apples and ornages. APPLES and ORANGES. But you want us to think that the apple is the orange and the orange works better. Wrong. Just to blow your mind though Chip came up with a fractalized VK2BDQ square almost 4 YEARS ago and it just sits in the notebook until he feels like letting people know. It's pretty and damn small too. Considering the harassment you've put on here along with your ilk is it no surprise that Chip is in no hurry to let lots of new ham designs get public attention any time soon? I mean to use Chip's words, "does their lunacy go as the arithmetic sum of new designs presented or to the power of new designs presented?" Right now it looks like a power. You've wanted and got your own worldwide forum OM. You really have thousands of people all over the world reading and some indeed buy into your 'mystique of doubt' just because someone who they've heard of says it.. Well you are very wrong and they should be irate at you for misleading them. I hope you e-mail box is full of their responses.

Look at how you've embarrassed yourself. This in one of many many chapters. Like not understanding what an error bar means and accusing Chip of cooking numbers, your alleged 'Chip entrapping interneters sting', your idiotic characterisations of me as Chip's "cabin boy" and "boy toy". There are many many more. Your abuse of freedom of speech is just inexcusable especially when you target someone with Chip's knowledge base helpfulness and integrity.

Phil

de N1ZKT

Thanks for your comments R___. Its important to protect intellectual property. Mr. R____'s post was not fair use. If he had asked and secured permission, and identified the source and permission given, then there would have been no problem. If the cost of such IP protection is loss of cusT__ers, then that is the price that any IP dominated company must pay. In fact, in the last three weeks there have been dramatic numbers of queries and web site hits, which tend to belie your impression. I myself have had to cancel my vacation, and as you might notice, spend relativelyy little time on the NG, with posts that are almost always under a minute to post. Lost a lot of sleep, but its envigorating. I am really enjoying myself with my work! It's exhausting but fun; one of the benefits is I meet some great people who I can help-- and learn from too. I can't say Mr. R____'s path down the black hole of malicious harassment has been a business booster, but the statistics certainly show a time correlation. Perhaps, if Mr. R____ wants things to 'go bad', he should just stop:-> Good luck with your antenna needs. Well, back to work!

73

Chip N1IR

T__--

I have NEVER used vulgarity. I would like to be be VERY CLEAR on the following: Any effort on your part--or anyone else's-- to harass me will be met by legal action. I have advised my associate dean of the harassment that my private posts have been subjected to and I am happy to advice university counsel of actions being taken by me, privately, to stop this abuse. Efforts taken to get me fired--which obviously is your intent Mr. R____-- will be met with full documentation--including the 'tanyaa' episode. If such action is taken on your part it will be made explicitly public on this newsgroup as an indication of your abusive efforts. Furthermore, I will summarize your actions and abuse for your employer in kind. In any case, I am most happy not to use profane language as I have yet to do so. Thus your request is extremely easily met. My requst is simple. STOP THE ABUSE

Chip

I am obligated to point out that a lawsuit is being prepared against Mr. S_____ and that I am under recommendation from my attorney not to respond to his posts. That lawsuit falls under the context of slander and libel. One need only briefly look at his posts (using dejanews) to get a sense of the harassment and accusatory defamation. In Proc ACES 1999, I had a paper presenting numerical simulations to show the role of self similarity and origin symmetry in frequency independence. I have, indeed, tested many antennas to this effect in the last few years. This was not done anechoically. My readily available resources for scientific investigation are, as I said, modest. It will be noted that this was done--and the post was presented here--for purposes of science. If a set of conditions is demonstrated in Maxwell's equations then they correspond to a property of nature. Thus the issue is iron-clad. Nonetheless, it is indeed valuable to do anechoic measurements, and I wish this were possible from this end. A vast body of new frequency independent designs arise from the new revising of Rumsey's Principle as Hohlfeld and Cohen invoke. Of course, only a fraction of given geometric forms have relevance to a specific application. Indeed, the log-periodic structures have been quite rich in applications. The point is that they will built upon as a body of design options, not supplanted.

With Best Regards,

Chip N1IR

Under advice from my attorney, I will not react to your new comments. Your continued statements place you in the situation discussed off line. It is up to you to seek out an attoprney's counsel on the matter. I remind you that statements such as "alleged PhD", and so on are deliberate efforts to publicly libel.I will repeat a general statement: Malicious libel is NOT acceptable. It can--AND WILL-- lead to litigation. FYI Mr. Oï¿½N___ and I are NOT presently, or planning for, litigation against each other. We resolved our differences reasonably. Furthermore, I have publicly asked for the matter to be dropped. Your continued, unwelcome statements go against my wishes.

Nathan Cohen, Ph.D.

Mr. S_____:

This week I will be writing to the Director of the Los Alamos National Laboratory (Dr. John Browne), and the two senators from New Mexico detailing the harassment and libel which you have inveighed against me. These include deliberate and malicious efforts to attempt to get me terminated from my academic position, and false misinformation regarding whether I 'deserve' to have the title Ph.D. , as well as false accusations that you are the inevntor of fractal antenna technology.These will also detail the assertions you have made stating that I am mentally ill. I will describe this inappropriate behavior with the intent to ask the question why someone with such a malicious and destructive focus against an individual should be in the responsible position of being involved with nuclear detonation

development.I have very serious concerns for my personal safety and that of the country if you can make false assertions freely while holding a position with severe and serious responsibility.

Nathan Cohen, Ph.D.

Mr. S_____ has posted an accurate copy of an e-mail I sent him. Mr. S_____ is a a developmental engineer/scientist at the detonation branch ofLos Alamos National Laboratory. He is involved with nuclear detonations, a high security clearance position.The wheels turn.

Ian Jackson, G3OHX wrote:
"This (on-channel relay) is obviously more effective than the passive arrangement, but you have to provide power."

With power, signal from an antenna amplifier at the remote site may be wired back to the receiver.

If wired transmission is impractical, a transmission frequency differing from the reception frequency may be used to eliminate feedback.

A heterodyne repeater can be as simple as the first detector in a superheterodyne receiver. No demodulation of picture or sound signals is required.

As far as I know, some "part 15" license-free provision may allow a microwave frequency to be used for the antenna relay. This could make dishes practical. Many 20 to 30 mile microwave paths use 100-milliwatt transmitters with excellent reliability.

Ian`s cross-polarization idea is good for a powered installation, same-frequency repeater. Also, repeater gain makes coax loss affordable. So, separate the input and output antennas of a same-frequency repeater by 2 wavelengths or more. There is 22 db loss in the first wavelength of separation between the antennas. You get 28 db isolation out of 2 wavelengths separation, and 34 db isolation out of 4 wavelengths separation. The point of diminishing returns from antenna separation is reached in a very short distance.

Best regards, Richard Harrison, KB5WZI

Roy,

I think a transmitter output impedance being in the baallpark of 50 ohms is a coincidence. In the formulas for matching the output of a transistor to a load, the real part of the output impedance does not enter into the calculations. If you consider that at the lower frequencies you can build a class B amplifier with 70+% efficiency, and a class C amp with 80+% efficiency, you know they can't be conjugate matched. I think transistor manufacturers add to the confusion by sometimes talking about ouutput impedance; when you read the fine print of the footnote, they explain that they are really talking about the conjugate of the desired LOAD impedance.

Oddly enough, the one place where you would think that conjugate matching is desirable - antenna to RF amp input, does not quite work either. That is because best noise figure does not coincide with maximum gain.

I think I would rather have a generator whose internal impedance is a small
fraction of the load impedance. The efficiency of a ham transmitter with
a 0.5 ohm internal impedance would be 99% into a 50 ohm load. :-)

He said pileups. How often do you hear U.S. stations pileup on other U.S. stations? Obviously he seems to mean dx. Model a dipole at 65 ft, and then model a vertical with 240 radials, and see which does better below 15 degrees. 6.5 dbi at 35 or so degrees won't do a heck of a lot of good when working dx that probably uses angles mainly below 15 degrees. Probably less than 10 degrees for far off stuff. No vertical is going to beat a dipole at 65 ft in all directions and distances. It's going to beat it by a healthy margin on long paths at the lower angles though. BTW, even though the modeling exercise will give the vertical the advantage below 15 degrees, I think the advantage is understated. I'm convinced most of the modeling programs understate the gains on many verticals. Elevated verticals really seem to lose out when modeled. I see many inconsistencies. Lets say a ground mount with 120 radials is appx equal to a ground plane at 1/2 wave up with 4 radials as far as ground losses. From all tests I've done, this seems to be true. In fact, many times the elevated antenna is the best, just being clear of the ground clutter. But model them and see the results. The GP will be slighted severely when modeled. "Houston, we have a problem"... If you use a mininec program to model a ground mount with 120 radials, you will see about 3.3 dbi or so. Model a GP at 1/2 wave with 4 radials and see what it gives you. You can use a mininec ground, or a nec4 high accuracy ground. Take your pick. The nec4 "should" be the most accurate on the elevated antenna I think. It would seem to be a pathetic antenna when modeled, but I'm about 90%

sure thats in error. The modeling programs are dropping the ball in that regard, and can't be trusted to give accurate results. That my opinion anyway...
Lets look at another problem...Model a GP at 1/4 wave, and then model one at 1/2 wave. Now, in the real world, I've rarely seen a GP at 1/2 wave lose to one at 1/4 wave in the real world, regardless of theoretical high angles. When you model the two, they give almost equal gains, with max gain at a high angle for the higher antenna. This doesn't seem quite right to me. You should see a bit larger increase in gain jumping up another 1/4 wave in height, I think. After all, this is the appx equal of converting a 60 radial ground mount to a 120 radial ground mount. You see the increase when modeling a ground mount, but you don't with the elevated. This increase in overall gain, due to lower ground losses, "should" give the lower "lesser" lobes on the 1/2 wave high antenna an increase enough to compete or even beat the 1/4 high antenna's low angle performance that it gets from it's "major" lobes. Or I think anyway...But it doesn't pan out in the models. Also, when I model my GP and my dipole, I have to "pump up" the ground cdx to see the same results on the model, as I did in the real world. Anyway, I think verticals are getting the short end of the stick on many of these modeling excercises and can't be totally trusted. If you model ground planes at very high heights in wavelength, the accuracy seems to improve to more what I would expect. IE: model a 2m 1/4 wave ground plane at 30 ft, and it seems pretty accurate to me. But it's multiple wavelengths up in the air. I think the programs are having problems dealing with elevated verticals under 1 wavelength in height above ground and giving them overly chinchy results. I may be wrong, but thats the way I see it. MK

> He said pileups.

Hi Mark, The sentence that caught my eye was the one quoted above.
I wasn't aware he was talking about *DX* pileups as he didn't mention
"DX" and did mention "local guys". I suspect there would be no contest
in a pileup with other stations at 500 mi. on 40m in the direction of
the dipole's broadside radiation.

One other nitpick. He said his 35 ft. monopole was "all-band". No
way will a 35 ft. monopole beat a dipole on 10m. The vertical has
a maximum gain of 3.8 dBi at 35 deg TOA. My 80m dipole has 10.8 dBi
maximum gain on 10m with a TOA of 12 deg, 7dB better on the gain and
23 degrees better on the take off angle for DX.

You're making the common mistake of assuming that a transmitter having an output impedance of R ohms has the same internal dissipation as a Thevenin source with R ohms impedance. Transmitters don't contain resistors, and the output impedance isn't determined by one. So it's entirely possible for a transmitter to have a 50 ohm output impedance and be 80% efficient when driving a 50 ohm load.

I'm not attempting to make the argument that transmitter output impedances are necessarily 50 ohms. But I am pointing out that a number of credible measurements have been made on commercial amplifiers which show them to be close to this value when adjusted for rated output power.

And I'm talking here about output impedance, not load impedance.

Hi Cecil,

Then you need only tap the transistor (not FET) stage BEFORE the bandswitched Low Pass Filter in the rig and BEFORE the impedance boosting transformer (often built with a binocular style feed).

Those bandswitched filters are built for 50 Ohm conditions (in and out) and the transformer is a step up from the several Ohms presented by the class AB stage driving it. Any casual review of the schematic of your rig, and standard design math will reveal this potential low Z source is easily available.

Useful is another matter. For in that combination of low pass filter and drive transformer are considerable benefit in meeting RFI requirements. That low Z source is chock full of severely distorted sine waves (if one could describe them as such). Being in a balanced design (the class AB bridge style), reduces a lot of this distortion through the combining effect of the transformer. The filter that follows does considerable work to reject the fast edges and backfill them into roughly sinusoidal shape.

You could, of course, choose to build a step-down transformer (to achieve your half Ohm specification, but you will still need a Low Pass Filter with a characteristic Z of that same 0.5 Ohm. With those two steps you will have the source you describe. Myself, I would skip the step-down and work on the amp to boost its distortion figure so I could skip the filter as well. A 2 to 5 Ohm source would be as effective in your characterization of efficiency. However, as nothing will have actually changed with the original circuitry driving any of these passive output channels - efficiency will remain at a pretty bland 45% or so.

As I remember, he didn't mention DX but did mention "local guys". Of
course, a well-designed monopole will beat a dipole at long distances.
But in the 500 mile range, I would expect the dipole to be better at
least in the dipole's favored directions.

One more nitpick. He said his 35 ft monopole was "all-band". I can
guarantee that a 10m dipole will beat a 35 ft monopole used on 10m
virtually 100% of the time.

I should add that you also have an option of going for a balanced
output from the get-go! That binocular transformer has a balanced
output UNTIL one side is tied to the common ground shared by the Low
Pass Filter it feeds.

Just unsolder that connection and instead route the transformer output
through a 50 Ohm balanced Low Pass Filter to your balanced 50 line.
Feel free to replace any occurrence of the number 50 with your own
characteristic Z. Feel free, that is, within the ability of an RF
transformer to efficiently achieve that ratio.

Hams used to do this - especially when these experiments so easily
reduced to ratios.

There's the curse of hamdom. The store-bought rig, and preserving its
"re-sale value." My shack is stocked with tough-dogs from the
boneyard and all rigs now meet or exceed their manufacturers'
performance specifications. (Caution, stunts performed by an expert,
amateurs should not attempt this at home.)

Heh. Unless you want to put long PVC pipes on all four corners, I'm not sure you could do it on a miata. ::Grin::

But it shows a decently efficient antenna setup for a mobile 18-wheeler without having to resort to monobanders, screwdrivers, or amplifiers.

Richard,

Assuming you have a 13.8 V power supply, the RF voltage at the collector of the transistor is about 9 VRMS. If you want 80W out, you have to connect 1 ohm across it. That's what the transformer does.

Roy,

I know you can do it. Worked with a guy who got a patent on a "bridge stabilized amplifier", which could be adjusted to have an arbitrary output impedance without adding loss. I just don't see that in any ham rig. What you do see is the sum of losses in the transistor, output circuitry, and filters.

Would any of you happen to have an operating manual for the MFJ-204B Antenna Bridge. I picked one up at a Hamfest but with no instructions. A scanned copy would be great. MFJ might send one in 4 weeks to life. Thanks & 73's.....Doug / WB3EGX

1442. Gain and efficiency

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-28 02:55:21 UTC
From: aunwin@insightbb.com
Message-ID: <85ed38d.0210271855.3f0d3f13@posting.google.com>
Source record: 132380

When using 'Gain' as a comparison term
many get mixed up with 'over ground',
'free space' e.t.c that lead to a non
real comparison as compared to a
particular radiator length at real height of say 25 metres
over a perfect ground. The reason I come to
re-examine 'gain' as we know it is because it ignors
turning radius or preferbly, gain per unit length.
For instance, a tribander for ten metres is
said to be roughly equal to a half wave element (dipole)
yet the tribander is using twice the turning radius,
because it has a part that is not radiating!
A Zepp which measures some where inbetween has more
gain than either of them and so is more efficient in
terms of unit length to either of them .
Even the latest antenna on the scene, the steppir,
states 'compared to a dipole' yet its turning radius
is DOUBLE that to which it is compared (ten metres) .
To call them "the same" is patently ridiculous
because the multibander is using a physical length
of twice the 1/2 wave dipole, which is so much more
inefficient per unit length.
As amateurs where most are constrained by antenna radius,
would it not be more reasonable to refer to efficiency
per 'unit length' where as more bands are created the more
the movement to multi frequency antennas?
Think about it, we think of gain as an order of merit
so the tribander with double the element length of a 1/2 wave
dipole has the SAME 'order of merit".
We complain of those who misuse 'gain' figures
as an order of merit where the average amateur is
more interested in max gain per turning radius (unit length)
over real ground.
Is it time to put our own house in order ?

Art

While a bit late, here's one possible antenna.
A 40 meter dipole, tuned for the center of the portion of the band you will be able to work, and an antenna tuner to use it on other bands.
I use a 40/20 dipole myself, and a tuner to use it on 80, and other bands.

I can, however, access my antenna, with a ladder, as I live in a mobile home.
The antenna is a 40 meter dipole, with an added set of wires for 20 meters, thus 40/20 dipole.
With the use of a tuner, I have tuned it on 80, 17, 15 and 10 meters.
I bypass the tuner on 40 and 20.
I have worked Russia (St. Petersburg) on 20 meters, from California, so antenna does work reasonably well.
With the higher elevation you'd have on the roof, you should do quite well.
Mine is less than 10 meters from the ground at the center, and ends droop from that point.

Good luck on your test(s)

Muito bem.

Not-so-small shielded loops may work better.

Search on "VLF loop". My search resulted in 4859 "hits".

Among items you will encounter is an "Octoloop" by William E. Payne, N4YWK. There are so many items other than the Octoloop, that there should be something suitable for anyone`s requirements.

Best regards, Richard Harrison, KB5WZI

I have a similar antenna (without the 20m wires) - a low 40m dipole with the ends lower than the centre.

The modeled driving point impedance is 8-j890 ohms at 3.7MHz. It is fed by 17m of RG6, which has a loss of 0.21dB at 3.6MHz. There is about 15dB loss on the feedline in the mismatched state, impedance seen at the ATU end of the feedline is 1.9+j7.9 ohms. A T match tuner should transform this to 50 ohms with a loss of around 4dB. Modeled antenna gain at 3.6MHz is about 3dB lower at 60deg elevation compared to performance at 7.1MHz.

So, all up, models indicate it is about 22db worse in performance than at 7.1MHz.

A listening test verifies poor performance.

Not sure what you are driving at.
The question is, shouldn't the tribander
be treated differently than a half wave dipole
beause it is much longer but only produces the gain
of a shorter element? Appears to me that there ia
a large difference in efficiency per unit length.

Do you mean 'tribander' or 'three element monoband yagi'?

> said to be roughly equal to a half wave element (dipole)
> yet the tribander is using twice the turning radius,
> because it has a part that is not radiating!

What do you mean by 'part that is not radiating'? The boom?

'Turning radius' is the amount of horizontal distance you would need
to rotate the antenna on a rotator. It has little to do with gain.

> A Zepp which measures some where inbetween has more
> gain than either of them and so is more efficient in
> terms of unit length to either of them .

Maybe so, but the 3 element yagi has a much better radiation pattern
than either.

> Even the latest antenna on the scene, the steppir,
> states 'compared to a dipole' yet its turning radius
> is DOUBLE that to which it is compared (ten metres) .

When an antenna is 'compared to a dipole' this does not mean that it
is the same as a dipole. It means that the dipole is used as a
reference, and the antenna being discussed is N times better than the
dipole.

> To call them "the same" is patently ridiculous

Electrical length is more important than physical length.

> As amateurs where most are constrained by antenna radius,
> would it not be more reasonable to refer to efficiency

> per 'unit length' where as more bands are created the more

Efficieny has to do with the resistive loss in the antenna.

> Think about it, we think of gain as an order of merit
> so the tribander with double the element length of a 1/2 wave
> dipole has the SAME 'order of merit".

If this was true, then why bother putting up a 'bigger' antenna?
Everyone would be doing moonbounce with dipoles! Again, the dipole is
used as a reference, which is not saying that it is the same as the
tribander.

That's just the opposite of what I've read. You might go to the Butternut site
at

http://www.bencher.com/pdf_download.html#tech_notes

and click on "tech notes" and look at some of their papers on radials. It'd be
interesting if Mr. Collins went against "conventional wisdom" on radials.

I think what Art is driving at is that with a trapped dipole, only part of the physical element is radiating (assuming a very good trap) om 10m. Likewise, the SteppIR fiberglas elements are always 36' long, even when using 6 meters, because the copper tape is varying in length inside. He is arguing for using the whole element on 15 & 10m...ie., .75 wavelength on 15m & 1 wavelength on 10m to get some additional collinear gain.

Not a bad sentiment, but difficult to achieve in a multiband, multi-element array.

I guess that would be an argument about the efficient use of space.

I don't get it.

The Steppir beam is just a mechanically controlled,tape measure Yagi-Uda. The element spacings are locked. It is very challenging to get those spacings to yield a co-linear element Yagi-Uda array with useful azimuthal pattern, if you let the element lengths get longer than an electrical half wave. You will get all kindsa lobes and degrade the end fire pattern substantially.

Like to see it if done.

Sure. It would be. In my case, rarely did the vertical win under 800
miles or so. There were some exceptions, but pretty rare.
>
> One more nitpick. He said his 35 ft monopole was "all-band". I can

> virtually 100% of the time.

Sure, a 35 ft vertical is way too long on 10m to avoid high angles of
radiation.
But when I hung out on 10m a lot, my preferred ant was a 5/8 ground
plane. I used to be on 10m a lot, and rarely did I use dipoles on that
band. They were ok, as long as the path was sky wave, but many of the
times I was working local way across town. But even on skywave across
the country the 5/8 ant usually beat dipoles. I compared them quite a
few times. I had the same results on 17m. The 40m ground plane I used
also doubled as a 5/8 on 17m. None of my wire antennas could beat it
on that band either, and it didn't matter what the path was. And some
of my wire antennas had gain in certain directions. Even in those
directions, they couldn't beat the 5/8 antenna. BTW, that antenna on
17m used 3/4 wave radials, not 1/4 wave. On that band, the antenna was
about 3/4 wave up in the air. So I think that helped matters some.
Same thing on 10m. I didn't use 1/4 wave radials there either. In
that case, the 10m 5/8 doubled as a 1/4 wave GP on 30m. Anyway, for
10m, I prefer a good ground plane anyday over a dipole. Many people
used dipoles on 10 when we hung out there. They were usually below
most of the people running decent verticals. Of course, almost nobody
ever used a ground mount vertical on 10m. They were all elevated. The
higher, the better. Most ran either 1/2 waves, or 5/8's. If you wanted
a BIG signal, you used a beam. MK

Source record: 132396

Ken,

If you can get into your transceiver and reduce the voltage to just the output amp you may be able to reduce the power from 3 watts to 2 watts without affecting the VFO operation as when reducing the voltage to all the circuitry. You'll have to check to make sure you aren't overdriving the output amp under those conditions. Another possibility is adding some inverse feedback to the power amp to reduce the gain. Using an attenuator as suggested by others will get the job done, but at the price of wasting power.

Hi Art,

Your nebulous style of writing offers many issues of wonderment. Efficiency per unit length? Why not efficiency per cubic mass? If one matters and the other doesn't, you are in trouble. Let's add another dimension of time and ponder the efficiency per Newton (your antenna moves doesn't it? or does the earth revolve around it?).

Don't you already treat a tribander differently? - we do - perhaps it's time for you to catch up with the rest of us so you wouldn't be plagued with these perceived problems.

We could also consider the implications of the Phonon disturbance, that comes with the eating of crackers, to the magnetic coupling fields. Certainly you can't reject that as just as important an issue as efficiency per calorie, can you?

1461. Tapped Coil vs Tuner on Vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-28 18:59:29 UTC
From: tayl0rr@yahoo.com
Message-ID: <ff33c2c3.0210281059.4ecded93@posting.google.com>
Source record: 132400

Which is preferable on a homebrew multiband vertical antenna. A tapped coil at the base or just a fixed length vertical with an antenna tuner? I'm thinking the tapped coil, with a tuner, but would like a little explanation if possible?

What band should the radials be set for? If full size radials are not possible should they just be made as long as possible?

Is there a faq for vertical antennas?

I would like to build a simple multiband antenna for 10-80 meter, but I have limited space, only about 30' horizontal for something like a dipole, but the neighbors wouldn't mind seeing a single vertical sticking up above the house 20-30'.

Thanks
Robert

From the 19th edition ARRL Antenna Book, page 3-3, "In general, a large number of radials (even though some or all of them must be short) is preferable to a few long radials for a vertical antenna mounted on the ground."

Or, from the "Why Radials?" technote at the Butternut site, page 3, "...but for a given number of wires the separation between adjacent wires necessarily

increases as the wires become longer, in which case currents on the surface between two highly-conductive wires must cross an ever-greater stretch of lossy earth to encounter a low-loss path home..."

Ken, KC2JDY wrote:
"Two watts is the maximum input.----It (Ten-Tec 1340 40M CW) puts out 3 watts."

You can use the reactance of a coupling capacitor to limit drive to the amplifier. A 1000pf capacitor has 23 ohms reactance at 7 MHz. A smaller capacitor has more reactance.

If the amplifier has a 50-ohm input resistor, nearly 1/3 the voltage will be dropped across the 1000pf coupling capacitor, limiting drive to 2 watts from a 3-watt source.

To further reduce drive under continuous control, add a 365pf variable capacitor shunting input to the amplifier. Several sections in parallel gives more control range.

Best regards, Richard Harrison, KB5WZI

Many programs have to be rewritten to work with Windows XP. Even Microsoft
sells different versions of Office for Win98 Vs WinXP.

Hi Jack,

Let's look at one of the several design claims:
>The top of the antenna is terminated with a solid aluminum static
>dissipating tip which also holds the four static dissipating hat wires. .
>These devices help the antenna dissipate static out of the air quieting
>the receiver and reducing the chance of a lightning strike.

In fact, casual observation of this end of the antenna reveals the
pointy elements claimed to be quietners (in sharp contrast to decades
of using large rounded elements that do exactly what is claimed). I
suppose in lightning saturated Florida it is difficult to separate out
the difference between static balls and static points on antennas.
Let's just say this design consideration is hardly worth the cost.

And then let's look at something that is more practical (because in
Florida there's no such thing as working, anti-lightning protection)
like the claim:
>A common flaw of the old style 5/8 wave ground planes were they
>radiated most of the power low in the element close to the radials.

With no actual discussion of what makes this a flaw, how large it is,
or what that flaw might be.

>Then putting the matching coil at the very base of the element didn't
>help the problem. In my new design top loading the element with
>inductance (coil) and capacitance (hat) correct this weakness.

As already noted, nothing as to how much this weakness has been
eliminated is shown, nor how much original weakness there was. In
fact, ALL of the commentary uses conventional gain figures WITH that
weakness (sic) built in.

Once you get past the blarney, the fact remains that the 5/8ths has
the same potential and that a simple 22 foot radiator and ground plane
with matching could do as well for far less than $145.00 Prospective
buyers should ask themselves why a 5/8ths antenna with a gamma match
needs other matching elements such as two coils and a capacitive hat -

except to boost profit or perhaps as a product of Antenna Optimization (whoops, such pseudo-science brings us back to the profit motive once again!).

I had trouble parsing Art's argument and, not knowing what a SteppIR
was, wasn't certain what he was getting at.

If I strung a 10 meter dipole between two trees 200 ft apart is the
antenna 200 feet long (by virtue of the rope used)? Of course not.
It is still only about 17 feet long. Also, the 'turning radius'
(which I took as being the physical---not electrical---size of the
antenna in his argument) has (almost) nothing to do with gain or
efficiency. You can easily build an antenna with a 2 inch turning
radius but 6 dB gain (stack 4 dipoles vertically). Lay it
horizontally and it will still have the same gain, but a 'turning
radius' of over 140 feet!

If he wants to change how people describe antennas, he will be going
against almost 100 years of established practice. Better to study
antenna theory first before attacking such a dragon, and gain a
knowledge of the incantations involved.

Maybe a good figure of merit would be gain per pound of metal used?

Well a dipole is a single element so for a tri bander I would be
referring to a single element tri bander, I have not made mention
of an array.

> > said to be roughly equal to a half wave element (dipole)
> > yet the tribander is using twice the turning radius,

>
>
> What do you mean by 'part that is not radiating'? The boom?

Very funny. When you have a tribander element and you use it on 10
metres
you do not use all the physical length. Radiation stops at the trap
after which the physical element is not radiating, very inefficient.
>
> 'Turning radius' is the amount of horizontal distance you would need

Maybe so, but the 3 element yagi has a much better radiation pattern
than either.

Probably but I have not refered to arrays at this time.

>
> > Even the latest antenna on the scene, the steppir,

> When an antenna is 'compared to a dipole' this does not mean that it
> is the same as a dipole. It means that the dipole is used as a
> reference, and the antenna being discussed is N times better than the
> dipole.

You are quite correct but when looking at an order of merit one must
consider turning radius and efficiency. If I made the tribander even
longer
by adding wood or something not conuctive at its ends should it be of
the same merit value of a tribander or a dipole or a dipole with
capacity hats at its ends ?

> > To call them "the same" is patently ridiculous
> > because the multibander is using a physical length
> > of twice the 1/2 wave dipole, which is so much more
> > inefficient per unit length.
>

Electrical length is more important than physical length.

Quite true, now you are comming around

> As amateurs where most are constrained by antenna radius,
> > would it not be more reasonable to refer to efficiency
> > per 'unit length' where as more bands are created the more
> > the movement to multi frequency antennas?

> Efficieny has to do with the resistive loss in the antenna.

Thats only part of it, you also can have cancellations that
produce less gains .The object I am looking at is gain and
the physical length to achieve that gain.
o

> > Think about it, we think of gain as an order of merit
> > so the tribander with double the element length of a 1/2 wave
> > dipole has the SAME 'order of merit".

If this was true, then why bother putting up a 'bigger' antenna?
Everyone would be doing moonbounce with dipoles! Again, the dipole
is
used as a reference, which is not saying that it is the same as the
tribander.

Bigger is not always better, especially if like a tri bander made
longer and bigger with the use of non radiating parts!

> > We complain of those who misuse 'gain' figures
> > as an order of merit where the average amateur is
> > more interested in max gain per turning radius (unit length)
> > over real ground.
> > Is it time to put our own house in order ?

> ...And maybe take a class in Antenna Theory first?

Now now Jim this is a discussion forum.
How do most of us measure gain compared to what is really relevant
which is how the element is used in practice.Manufacturers, scientists
and even computations can use 'ficticious' gains that you cannot
measure
while it is in use. It doesn't show on the meter. Antenna theory is
fine but not really practicable when measuring in the real world
Jim
N8EE

Jim Ihave only provided a tickler for thought, no body likes change
so everybody uses different terms where all can justify its merits.
At the moment we ignor efficiency yet we all know that the ends of a
radiator
are the most inefficient portion of a half wave radiator when
comparing
to unit length.

Roy Lewallen, W7EL wrote:
"And I`m talking here about output impedance, not load impedance
(regarding 50-ohm transmitter output)."

Yes.

Recall the breaker points in the Kettering automotive ignition system (the kind used before electronic ignition arrived). Contact resistance is almost zero when points are closed so the points won`t burn. When the points are open they have no loss either.

A "dwell meter" is used to determine what percent of the time the points are closed while the engine is turning. It`s simply an indication of the average current through the dwell meter during the making and breaking of the points. It is calibrated to read 100% when the engine is stopped with ignition current flowing through the closed ignition points.

The calibrated dwell meter would also read some value less than 100% were some resistance added to the point circuit. Current through the resistance would represent a real loss as indicated on the dwell meter, still representing less than complete conductance.

The calibration of the dwell meter just sets the meter to read 100% when the points are closed without any added resistance in the point circuit. The meter reads average current when the points are making and breaking.

The reduction from 100% dwell is normally caused by ignition current interruptions, not by a resistance voltage drop, so there is no loss from this "lossless resistance" which reduces average current.

"Class C", and to a lesser extent "Class B" amplifiers operate much like the breaker points in a Kettering ignition system. These amplifiers interrupt d-c current flow at the r-f rate. When they are turned-off for part of each cycle they are drawing no current and have no dissipation. When they are turned-on, dissipation is low due to their high conductance. The output resistance of these amplifiers mostly does not come from internal dissipation, but from their switched-off times. The interruption of current to the amplifier has the same effect of increasing output impedance as opening ignition points has in the automotive ignition system.

Robert,
Using a tapped coil at the base of the vertical
would eliminate or reduce losses in the feed line.
It also makes it a bit more inconvenient because you
have to go out to change the tap when changing bands.
So, which would you rather do?

Look in the "Yellow Pages" of a large city nearby for steel suppliers. Ask for steel tubing with the diameter, wall thickness and yield strength you need. In almost every city there is one (or sometimes more) dealer which will sell small quantities of steel to walk in retail customers.

Source record: 132418

I live in an area that has a fair amount of wildlife, and have had problems with gophers (I assume) chewing on buried and surface cables. They seem to be attracted to current, even at low levels. The only type of cable they don't seem to mess with is shielded direct burial cable. That stuff has a very hard, thick jacket. Before I install 150 feet of expensive coax for an HF antenna, I wanted to ask if anyone has had problems with rodents chewing their coax.

I know conduit would prevent wire chewing, but it is so much easier to lay the coax on the ground.

Unfortunately, Mike, it pays to use PVC pipe.

As soon as even a little nibble is done on the jacket, water seeps in and destroys the coax. Its slow, but a year may go by until you wonder why the SWR is so good but you can't break pile ups anymore...

Water seepage is the real problem. The critters are just the delivery system.

Try renting a Ditch Witch and the pipe will go in pronto.

PVC or metallic pipe underground prevents physical damage to the coax from rodents, pitch forkes, shovels, etc.

Hi Guys.
Oh Dear!! hasn't anyone heard of a Z match tuner these days!
I've used the G5RV for 30 years and have DXCC and WAC with it. Never running more than 100 watts. All it needs, especially with modern solid state rigs is a Z match tuner (see the old RSGB ham handbook).
With a 102 Ft G5RV you don't just have effectively unity SWR and a genuine 50 Ohm load on all bands but you also have a very good all band SWBC receiving antenna as well.
I haven't tried the 204 Ft version myself as I've never had enough room for one but I guess it would be even better on 160 and 80 metres especially.
Years ago I used the original design with 34 Ft of open wire feeders with coax on the end but I never really found it as satisfactory.
On 20 metres CW it takes a lot of beating especially as a transmitting antenna. I used to use the G5RV on TX and a phased 5/8 vertical array for RX 30 years ago and used to work the antipodes of NZ (Spain and the western Med) when 20 was apparently dead, in the early afternoon local time.
Just recently I worked a Bulgarian station while using an ARRL 1934 2 tube receiver on my G5RV.
For someone like myself who has always been an experimenter the G5RV takes a lot of beating.

Regards Cliff Wright ZL1BDA ex G3NIA.

Richard there you go again trying to appear extremely smart and deride
anything that does not appear to be up to your standards. I remember
sometime ago that you rejected gain terminology because it was not the
one you like to use.
Another time you recognised that you can get get bidirectional field
patterns
using a phase change on an element that is longer than a half wave and

then pronounced that it could not possibly provide extra
gain.Presumably you reject
that a extended zepp cannot get extra gain by providing two half wave
in phase.
I can therefore understand that you cannot except that an element on a
tribander can provide more gain by using all the physical length to
radiate.
But for those who are willing to discuss things with an open mind
order of merit
is a legitamate discussion where it provides a basis for comparison.
Certainly if a multi band element (tri bander?) is able to use ALL of
its physical length to radiate instead of stopping radiation by the
use of a trap e.t.c then I would consider that should have a better
order of merit.
If you want to suggest a counter proposal of ' efficiency per calorie'
then be my guest. But if you hold on to your prestated ideas that a
'collinear'pattern does NOT provide more gain than a dipole using the
same physical length used in a multibander you would be better off
studying shakespeare instead of deriding others. On the other hand you
could provide interesting responses both for and against. Have you no
ideas regarding order of merit at all?

> this to 50 ohms with a loss of around 4dB.

I haven't checked your antenna impedance or feedline loss figures, nor the impedance seen at the end of the feedline. These figures don't surprise me.

Note that 1.9 ohms resistance in series with 7.9 ohms inductive reactance looks like 34.75 ohms resistance in parallel with 8.36 ohms inductive reactance.

An L section should do considerably better than the T match tuner. You would want an effective Q of about 5, so build out the load with an additional 1.66 ohms of inductive reactance or so. That would be about 0.073 microhenrys, pretty small, but even if the coil had a Q of only say 10 it would merely increase the loss a small fraction of a db. The shunt capacitor would then be about 10 ohms reactance or about 0.0044 microfarad and of course it would have to handle quite a lot of current if the power was at all high. A great huge 1950s transmitting mica capacitor might be OK.

If you skipped using the series inductor and just used a shunt capacitor with about 8.36 ohms reactance (about 0.0053 microfarad) the resulting impedance would be about 35 ohms, and that shouldn't displease the transmitter too much.

Perhaps a slightly longer piece of coax would change R+jX from the 1.9+j7.9 value just enough so as to look exactly like 50 ohms in parallel with a certain amount of inductance, and then a single shunt capacitor would get you exactly 50 ohms.

Never use three components when two, or better yet one, will do. When your antenna is that poor, and your feedline loss is that high, every little bit helps.

I leave it to CAM W5DXP to work out how to do it with open wire instead of coax.

This sounds like my QTH. I was given a newtronics/hustler 5BTV. I have a ground wire going down to a 4' ground rod. (not the best setup, but it works) Between the TenTec 1251 RF counterpoise and the MFJ or LDG tuners, it does the job. I wish I could setup radials but that is almost impossible. It is a miracle I haven't been told to remove this thing yet.:-)

"Crazy George" is correct.
While you are at it you might want to check into Chromo (AKA 4130) steel.
It is quite a bit stronger per a given wall thickness.

Speaking of using different terms. . .

"Efficiency" has a very well known and universally accepted definition when applied to antennas: it's the fraction of applied power which is radiated. By this definition, an antenna having portions which don't radiate isn't necessarily any less efficient than one in which every part radiates. So if you choose to use "efficiency" in any way other than the accepted manner, please very carefully define what you mean, and note that you're using the term in an unconventional manner. Otherwise you're certain to fail to communicate.

A lot of people are perfectly glad to increase the turning radius of an antenna to pick up some gain, front/back ratio, bandwidth, beamwidth, or other desirable characteristic. And in each situation, one set of characteristics is more important than others, but the set can be different in each case. So making any kind of "figure of merit" or pseudo-gain or -efficiency from combinations particularly important to you is a useless enterprise, no matter how much fun it might be.

Advertisers are fond of inventing a problem, then presenting their product as the solution. And computer hardware and software vendors are fond of creating benchmark tests to show that their product is superior, even though all they prove is that the product is superior in solving a problem carefully contrived to show it in the most favorable light. I sense that's what's happening here.

The reason everyone isn't jumping on the bandwagon to embrace your concept isn't that they don't "like change". It's that it serves no useful purpose for hardly anyone. Everyone and every situation has its own set of factors that are important, so your "figure of merit", pseudo-gain or whatever, is useless to someone else to whom other factors are important.

Hello,

A antenna tuner is a circuit of variable capacitance and variable inductance. A antenna system and feedline that are NOT properly matched to the transmitter will have capacitive reactance or inductive reactance in the circuit. Typically there will be a combination of inductive and capacitive reactance present. The tuner is used to balance or cancel out the reactances. A tuner basically tricks the transmitter into seeing a purely 50 ohm resistive load. A tuner presents its share of problems also. A tuner increases losses in your system but it gives you more flexibility for various band operating. The ideal (in my case, dream...8)) situation would be to have a seperate antenna for each band that would be resistively matched to my transmitter without the need for a tuner. I do not own several acres for a antenna farm so I must accept the tuner losses for multiband single antenna flexibility. A tuner in no way will improve your SWR from the tuner output to the antenna. It improves your SWR from tuner input to your transmitter.

the word is accept (and yes I except which is the opposite of cannot
except).

>tribander can provide more gain by using all the physical length to
>radiate.

Hi Art,

This is the height of ridiculousness.

You are using what is called the Strawman argument. You alone have
made the choice of this so-called "tribander." You seem to be more
than willing to use terms of your own invention and sit back wandering
why no one understands - it is worse when you use existing terms with
new meanings. You would gain much if you observed other advice here
to study the topic.

But let's get back to this Strawman of your choice - tribander.

It is obvious that you have chosen a poor example to take apart that
allows you to then make a discovery hidden to us all (yeah, sure).

>tribander can provide more gain by using all the physical length to
>radiate.

This obviously begs the question: why did you make this poor choice in the first place? Imagine indeed those pitiful, useless two outboard sections that do nothing for the top band operation! Art, can you imagine WHY they call it a tribander? If only they would just go away so they did not upset the turning radius! Only the kid in the street would notice the King had no clothes on. You chose the "tribander" to only condemn it for having other elements to cover two more bands? That is precious by half. Is the next thing on the plate trying to convince us that the 10M section with its 10M trap is enough - why don't we just cut off the rest?

Art, I know what you are talking about. It is poor set-up for your half thought out propositions where you have to cleverly craft a problem your invention will solve. The problem with THAT problem is that no one suffers it because they have the smarts to stay away from it in the first place. Folks here and around have already optimized their antennas for maximum turning radius efficiency - Hams in general aren't the hayseeds you seek to convert.

Actually US$12.99
www.radioshack.com
Type in product number 22-410 at the top
(specs*, hole template)

* Interesting note: "You must connect the 15 kOhm resistor (supplied)
between the voltmeter and the voltage supply being measured." (.: 1mA
movement.)

or Cdn$17.99 in Canada
www.radioshack.ca/estore/Product.aspx?product=2200410
(nice big picture)

These exact meters were being sold for Cdn$3 a few months back during their
'Inventory Blowout' (at least in Canada). Ask around and maybe you'll find
someone that bought several because they couldn't resist a deal.

Hi gang,

I am putting up a Glen Martin roof mounted tower that will put my Hexbeam up at 32' (Incidentally, the Hexbeam performs a little better than my inverted V dipole at 30'... and the Hexbeam is only 8' off the ground at this time! I cannot imagine what this thing will do at 32'!) I will have the Hexbeam that can do 20-10M so that will give me the beam capability. My inverted V dipole is a DXLB+ that will be mounted at 32' at the apex (using the tower). This will cover 160-10 minus WARC bands (which will allow me to do state side QSO's). I am considering adding a GAP Eagle DX to my antenna list. I have a friend that will sell his for a good price (he is upgrading to a tower). I used to own one and I had a bad time with it (which I think it was operator error because the coax connector was not solidly soldered to the feedline of the antenna.) The guy I sold it too is having a great time with it and it is performing very well for him (in fact, his location is worse than mine!!) So I am considering giving it another chance.

So my question is this, would a bad solder joint cause the antenna to be a poor performer? The guy who bought my original Eagle DX pulled the coax connector right off with little effort. The copper braid in the coax was black for about 6". With a properly soldered coax connector, would this make a difference?

Second question, adding the vertical... would this give me a well rounded selection of antennas? (Beam, dipole, vertical).

Thanks es 73!

A mismatched system can also be purely resistive -- that is, with no reactance -- but the wrong resistance. Admittedly, though, this condition is uncommon when dealing with antennas.

> Typically there will be a combination
> of inductive and capacitive reactance present.

One is simply the negative of the other, and the two add up to a single value. For example, 200 ohms of inductive reactance + 50 ohms of capacitive reactance can be written j200 + (-j50) = j150 ohms which is 150 ohms of inductive reactance. 200 ohms of inductive reactance + 300 ohms of capacitive reactance = j200 + (-j300) = -j100 ohms, or 100 ohms of capacitive reactance. So although there might be several or many capacitive or inductive components in a circuit, there's only a single resulting value of reactance, which can be positive (inductive) or negative (capacitive).

The tuner is used to

Hi Jason,

I've had one up for nearly 10 years. Elevated 10 or 12 feet and
anchored to the corner of a carport, it has operated satisfactorily on
its higher bands. Facing SW into the weather, it has stood all the
strongest winds without guying. Wind has broken 4 of my Maples in
that same time.

You could have twisted wires together and had better conductivity IF
you had weather sealed the connection. From the description of the
condition of the connection, it sounds like you needed a good solder
job, a good seal job, and a good strain-relief job.

You going to hoist this to the top of your new tower?

Well it does appear that way, again antenna confusion.
Don't manufactures sell single element tribanders?
What about two element forms ? If I mentioned comparing
multi elements to single elements then I caused the confusion.
But it does appear that most hams have no interest in
antenna efficiency, thus I am out of step with the majority.
On the other hand if any multiband antenna, single element or
otherwise uses a turning radius which is only used effectively
for one band, then it behooves all antenna people to strive to use
the unused inert length as part of the radiator and thus increase
the gain for the majority of frequencies.This to my mind increases the antenna
gain which thus increases the efficiency with respect to unit length.
Chip made the point that this sort of pursuit will just form multi
lobes which ofcourse is incorrect. When a phase change is incorporated
so that the inert lengths radiate it can increase the gain.
I am pleasantly pleased that some posters are not following the
slamming aproach and sticking to polite antenna type responses.
Good on you Doc

> An L section should do considerably better than the T match tuner. You

Yes, you are correct in that a well implemented L match is likely to be
better than a similarly implemented T match for such a load. I used a T
match example because that is what most people tend to use as a
"universal" fix it for antenna design problems. The 4000pF required for
an L match is also potentially an issue.

But, my observation was that whilst a 40m dipole fed with coax might
work quite well on 40, you cant just wack a tuner on the tx end of the
coax and expect the combination to work well on 80m, indeed it might
work quite poorly... and no tx end tuner configuration can fix up the
problem that the coax operates at very high VSWR and even moderately
good coax will exhibit very high loss in that situation.

Locate and check with the local ham clubs. I have acquired four used but like new Tri-Ex crank up towers from older hams that were moving out of state and wanted to give them to anybody that would take them down and remove them from their property (one was a fully motorized crank down/fold over 70 footer with a Ham IV rotor and all control boxes and cables).

I have also passed on numerous other free or nearly free towers just because I am running out of room to store them... :>)

>mine) and seems to be a very sound and easy one to follow. Put
>radials down in such a way that the distance between their tips is not
>more than 0.015 lambda."

Several people have done the same, by looking at the experimental graphs of feedpoint resistance versus length and density of radials. All the graphs curve over when you've laid "enough wire", and then you enter a region of diminishing returns. The transition points from whole families of curves all correlate pretty well with a tip-to-tip spacing of about 0.01-0.02 wavelengths.

That makes some sense, because the spacing between the wires will affect how much the fields can induce return currents in the lossy ground instead of taking the preferred route along your wires. In the nature of radial lines, the spacing near to the centre will be closer than needed, so it's only out at the tips that the effect will show.

However, all this business about how best to use a given total length of wire is academic. Wire's cheap, and in most people's backyards the practical limitations are property boundaries, solid obstructions and backache.

But your mileage may vary... in this case quite literally!

Art...I understand conceptually what you are trying to convey...that it's important to you what the gain is per unit of length (in wavelengths). Unfortunately, electrically using all the element in a 36' long radiator to get extra gain on 15 and 10 will not give a higher gain per unit-length.

For instance...

Gain on 20 would be 2.1 dbi, gain on 10 would be 3.7 dbi when properly fed. You have doubled the length, but have only increased gain by a factor of ~1.45. Therefore, your gain/unit-length (or FOM, or length efficiency, or whatever you might want to call it) based on the above metric, and using a full size dipole as the reference would be..

1.0 for the dipole
1.45/2.0 = .7225 for the collinear dipoles.

In fact, a short dipole...say .25 wavelength long...would outperform either of the longer ones based on that metric. Gain of the short dipole would be ~1.1 dbi assuming a loading coil with a Q of 200 and a 1" element dia.

That would give a ratio of .79/.5=1.58 for the short dipole.

So, the short dipole with only 1.1dbi gain would have a higher gain/unit-length than either of the others. It could easily be shown that gain/unit-length would keep increasing as the element got shorter up to the point where losses in the loading coil would become excessive...even though total gain would be steadily decreasing.

In the case where you count the entire length, even if it doesn't radiate...as in a tri-band trap dipole...you would admittedly get slightly more gain/unit length...

.5 for dipole
.7225 for collinear dipoles...

But...

Using the gain/unit-length metric, and carrying the argument to its absurb conclusion, to make really "efficient" (length-wise) use of the whole element, instead of trying to use the entirety of a 20m element on 10m...it would make more sense to load a 10m element on 20m ;-)

This obviously only makes sense if size is the most important parameter.

Consult Dorothy`s swap net on 2 meters or almost any of the many 2-meter nets on area repeaters. Most have a sell, swap, or trade segment.

It's arguable that squirrels are the worst! No only do they nibble at what is on the ground, but they chew holes in the insulation and shield from what is up in the air as well! Over many, many attacks and years of 'em I've discovered a couple of things. First, they almost never chew on anything but horizontal runs of the coax! If you pay attention to them in the city environment, they use the phone cables and so on as aerial tramways. Only in the ham radio venue, a coax line strung horizontally will almost always wind up with holes in it! They wander down it .. and chew too! Not all the time! You will discover that if you bind a guy wire to the horizontal run with weatherproof tie wraps and use it together with the coax, they will virtually always leave the pair alone and not nibble on it!

The second interesting tactic you can take to reduce the damage comes from a separate factoid. If you look at lots of hits, you will discover that they almost always do not go after the OLD cable! It is only the new stuff! Sniff... But wait, there's more here! You'll discover that you can take a rag full of Tabasco sauce, the hottest stuff you can find. soak the cable with full coverage of the infernal stuff after/as it goes up or down on the ground.

Yep! It seems to repell the varmints. That lesson learned, you can take an insecticide sprayer. Make up a strong brew of the evil stuff and liquid dishwasher soap for an emulsion ... giggle. Wander around spraying the cable on the ground with the brew every now and then. They do not apparently like Tabasco sauce and will leave you nice cable alone. As the cable ages and the strong odor of the new vinyl decays normally, they will usually leave it alone. From my experience it is the odor of the casing that seems to attract them to chew on it.

Just like deer around a watermelon patch, all they want to do is poke holes in it! Ever watch deer in a melon patch? They'll poke a hole in melon after melon with a hoof and sniff-sample every one of them. Never eat really anything.

Can't say my suggestions totally stop the pests for coax left laying around lose, but it works well here.

Brilliant response, so well thought out.
Yes I am interested in radiator unit lengths because the majority of
hams
do not have the luxury of large plots of land, so getting the maximum
gain
given their lot size, is the primary goal.
Your point on shortened radiators gets to the very heart of
obtaining
maximum gain per unit length. Zukov stated that maximimum efficiency
is when radiation efficiency is from a single point, obviously he was
extrapolating from the fact that max radiation efficiency per unit
length is at the peak current point, and with that in mind efficiency
per unit length can be gained by removing the radiator ends (capacitor
hats e.t.c.) or changing the phase at judicious points.
Thanks Larry

Art,

Yes, my questions were sincere. I read your post 3 times before I responded. Even then I did not entirely understand what you were saying.

As others have pointed out, you used unconventional definitions for common terms, so naturaly it will be difficult for everyone to understand. In order to communicate ideas effectively we must all agree to a common language.

I have hesitated on this group to 'wave my own flag' because I do not want to sound arrogant, but I have been an engineer for almost 30 years, and a Ham for longer than that. One of the first 'rules' of engineering, that every engineer must know, is that you first study how and why things are done the way they are. ("Those who ignore history are condemed to relive it.") Only then are you prepared to do something new, and any engineering invention is a compromise between requirements. Why some of us appear smarter than others is not that we are more intelligent (hmm, well maybe some of us are ;-)) but we have years and decades of experience in learning the hows and whys of the way things work.

On to antennas...

An antenna does not create energy. When an antenna is said to have gain, what that means is that energy is 'borrowed' from one direction and 'directed' in another direction. A 20 dB gain antenna does not radiate any more energy than a 3 dB gain antenna (with the same transmit power). As I stated previously, all antennas are a compromise between requirements. There is no perfect antenna.

The triband trap dipole that you describe was designed with these compromises in mind. It is a relatively inexpensive low gain bidirectional antenna that will work on three bands. On each band it is essentially a half-wave dipole. For ease of use, it was designed to work with standard 50 ohm coax. Change any part of the design and it would no longer meet its purpose. Instead of thinking of the outside parts being wasted on 10 meters, why not think of the 10 meter part being used to hold up the 15 and 20 meter section? In that way,

the antenna has a higher 'figure of merit'. You get 2 extra bands for a little more than the cost of a 20 meter dipole.

As another post pointed out, 'efficiency' is a measure of how much energy is radiated vs how much is applied to an antenna. If you try to compare a dipole with an extended double Zepp, the Zepp will have more gain, but is not necessarily more efficient. You should also consider the matching network required to allow the use of 50 ohm coax. It will certainly subtract from the efficiency.

For some reason animals are attracted to new PVC.

We have had problems in the past with our cat chewing practically
every electric cord we have, particularly brand new ones.

Many years ago our high school ham club did the early set up for field
day, complete with brand new coax. When we went back the next weekend
for the contest we found that the coax was full of teeth marks.

We are looking at building a new home. Other than deed prohibitions, what do I need to look at having done to make life easier for my radios? Is there some type of built in I can have installed to pass coax etc into the shack? Normal conduit would never fit the needed coax. Should I prewire coax runs through the walls and then join them to the antenna line to come in or how do most do this. I have drilled and pulled so many runs of coax and cat 5 and telephone in the last year that I hope to make things easier this time building from the ground up.

==========

An "un-un" in that application serves no useful purpose. Who told you otherwise ? An "un-un" salesman ? An old-wife who has been conned by the "un-un" adverts but who has never used one ?

If you use a ring of power supply grade you will certainly introduce a loss which increases with frequency.

If you MUST introduce a gadget between the random wire and a receiver then buy or make a simple preselector. (If your receiver does not have one already built in.) Depending on receiver performance without a preselector there may be a considerable advantage in using one.

A preselector helps to prevent the many strong signals, to which the receiver is NOT tuned, from over-loading the receiver input and causing interference with weak wanted signals to which the receiver IS tuned.

Don't bother with a "tuner" intended only to transform the input impedance of an antenna to 50 ohms. The amount of pre-selectivity it may introduce is negligible.

Must have been soft and chewy with a polyfoam nougat center! mmmMMM!

If someone can figure out why animals eat what they eat, it would solve one of those cosmic puzzles.

My speculation is that rodents eat this stuff because they have a prime directive to eat anything...and that the time scale for getting cancer from it is longer than their lifetimes.

Its a huge recycling act of organic material.

BTW, Mike's Tabasco suggestion sounds great and indicates the lack of taste of the rodentia. It also explains why my peppers can dry on the vine for months and months and months.

Friend used 2 inch PVC in the walls. He modified a 4x4 plastic electrical box (cut hole and glued a fitting on it. used a plastic cover. Drilled to let cable enter the room. Use a 4x4 at the turns in the conduit in the attic and to use as a pull box. This did limit him to, I seem to remember to 3 RG-1 sized cables.

Deed restrictions are the big bugaboo since PRB-1 specifically excludes them. The one I ran into wasn't against antennas, it was against "structures more than one story tall without prior written permission from the architecture control committee." So READ CAREFULLY! (In our case, we had prior written permission before buying our lot.) One neighbor decided he wanted our lot and used my proposed two vertical antennas to start a campaign to drive us off and the architecture committee withdrew its approval. We could have gone to court and probably forced him to reinstate it but decided we didn't want to live in that particular community of assholes. Sold the lot (not to the neighbor) at double what it cost us and left.

I know of other cases where cities and counties have issued permits, then withdrew them part way through tower construction, so there are no guarantees. It's a minefield out there!

Look also at your community (city and county) ordinances... they can contain height limitations and/or specific antenna restrictions. This is the one PRB-1 can help with but it can be a lengthy (and costly if a court is involved) process.

Or, just do what we did... move out to the country on a little acreage. ;-) I've been a city boy all my 65 years. Didn't think I'd ever take to country living. Wife talked me into it. So far, we're absolutely loving it! Peaceful. Quiet. No traffic. Scenic. No pollution. No light pollution. NO TRACE of radio noise. I'm feeling more laid-back than I can ever remember.

>
>
> Jim
> N8EE

Yes Jim I have studied antenna theory so maybe this is a good time
to bring you up to par
The first run at antennas was to form a long wire as an antenna
but it was found that certain parts of the antenna produced
subtractive gains and the Yagi provided a solution for that which
started down the road to the ideal situation of getting maximum
efficiency by reducing element lengths down to a single point as
with a flash light or a lazer. There are a few attempting this pursuit
such as the EH antenna, the contra-wound and yes even the fractal.
In the main however the hobby has gyrated to bigger is better
regardless of efficiency. We also ignore aproaches to simplify our
construction of antennas of which enough is known to tell us that
only skin depth is of real concern and we should wean away from
aluminium tubing to lighter materials to carry the skin.
Of course many attempts of improvement fail but snide remarks do
not help. I was particular interested in how one person added
capacitors along the length of a antenna in a attempt to install many
phase changes in the hope that the radiation current curve would
become a straight line, A wonderfull concept that was poorly thout out.
Ofcource we do have examples where people have nullified negative radiation
such as the extended zepp ie. better efficiency tho I am bewildered why
capacity hats are not used. We also have long wires (bobtail) that
does a similar thing making use of phase changes to remove negative
radiation and increaseefficiency per unit lengtjh.

Scott, all I have to ask is "what are you prepared to spend?"

My take on this is "Safety First." Figure out where your house
electrical ground is supposed to be. Invest in a really nice ground
system, not just what's legal under your local electrical codes.

Then, set up an antenna cable entrance plate. If your station is in
the basement this can work very nicely by placing said entrance next
to the ground system. Place all your lightning arrestors and antenna
switches on this entrance plate and then attach one very short,
straight ground strap to the house electrical ground.

Plan on keeping the antennas away from the house. If I were in your
shoes, I'd plan on a set of steel conduits to whatever towers you may
use. Take care to seal up those conduits with something that critters
don't like. You could try spraying lots of hot sauce in to the
electrician's putty and using that to seal up the conduit.

As a "just for grins" system, consider a separate DC battery system
with a battery charger on a timer designed to float charge the
batteries. This will give you emergency power, it will effectively
isolate your shack electrical system from the rest of the house and
it's not particularly expensive.

>
>
> Jim
> N8EE

Ooops, the other posting slipped away without me finishing.
So to continue
My object in antennas centers on efficiency
per unit length (gain) in a similar fashion as the zepp but to make
radiating length irrelevent (A loop does this also)
When I achieved this and shared the concept some treated it
as heresy and derided me in the hope that I could be burned
at the stake. Eventually somebody modelled it and confirmed
that it stayed bi directional even tho frequency changed.
Some reluctently agreed that I had achieved my aim but then
sniping occured again when I committed heresy by pointing
to my increased gain, when I thought all understood that phasing
produces gain per unit length i.e. the collinear gain aproach
So yes I understand antennas and am pushing the envelope
with respect to efficiency and unit length, you have the choice
of proving me as an idiot but I am not Joan of Arc that will
allow you to burn me at the stake. So why don't we stop this
pattern of slamming people in this antenna group for one reason
or another in futile attempts to muzzle.
If you really believe that I am deficient in knoweledge and
should study up more on antennas, be a bit more constructive
so that interchange can be more pleasant.
Best regards
Art Unwin KB9MZ......XG
in your response.

Hi Art,

I can walk too (you certainly make a lot of presumptions). You are right about the rest of the nut fringe getting a vacation (but that actually comes from the general vacuity they present - their nature abhors facts).

One thing about my comments and the content of the archive, as you put it, there are few genuinely prepared to respond to them in either english or technical and your correspondence is certainly a hallmark of this trend. Do you except this? ;-)

Do mean a voltmeter or just a meter movement?

If you want just a panel mounted meter movement, most of them measure current, from a few microamps to a few hundred milliamps. To measure voltage you have to put a resistor of the proper value in series.

Don't be fooled by what the numbers are on the face of the meter. That is just a little piece of paper, and does not directly reflect the range of the movement. However, there are usually some tiny numbers in one corner that will tell you the actual characteristics.

To make the numbers on the piece of paper meaningful you have to use the characteristics to calculate the required resistor (for measuring voltage). For example, if the characteristics say '10 mA FS 1kohm' and you want full scale to be 15 volts, that means it has a resistance itself of 1k Ohm and 10 mA will cause full scale deflection. You will then need an external 1k resistor (in series) for full scale to be 20 volts.

If you can't find a meter with the correct scale printed on it, make you own. I think there was a post on rec.amateur.homebrew a short time ago on this topic.

Source record: 132278

I am interested in JPole antenna because I support a manned gas (hydrogen) balloon that participates in long distance (100's of miles or more) competition. I need to support voice communications in the 154MHz region at about 10 watts, APRS transmissions in the 2Meter Ham band at 5 watts and Aircraft communications in the 123MHz region at 10 watts occasionally boosted to 20 watts if needed. The average altitude for the balloon is 5-6000 feet but can range up to 15,000 feet and down to 2-300 feet. For many years we have used dipoles worked fine but were "spikey" in the physical sense that subjected the balloon and crew (2 man) to possible physical injury especially during launch and landing. I got onto JPoles two years ago because they could be fabricated from TV Twin Lead and a length of coax. They proved to be safer and were cheap to build. The JPoles were also somewhat luighter than the dipole stuff we were using which was a small bonus.

I would like to hear some comments concerning their use and usefulness.

Any enlightenment will be appreciated.

Vic

1541. when does small size really reduce radiation?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-10-29 20:12:17 UTC
From: Henrik <henrik>
Message-ID: <3dbeeba0$0$34825$edfadb0f@dspool01.news.tele.dk>
Source record: 132280

Hi,
having invested in an automatic tuner (SG-239), I am wondering about the needs of size to secure radiation efficiency....

It made a big impression on me to read an earlier mail here from "Reg", to high pressure clean your brain of the magic of the G5RV....and just erect the biggest dipole as high as possible.....as I really feel we have a statement of general truth here!

I would appreciate comments to the above statement, when I use the tuner (coax fed) at the aerial....what it brings to make a loop (in the same space) compared to the dipole.....with the view to secure highest possible radiation of RF, and quietness of reception.

When does size really become critical...is it the 1/3 of a wavelength for both elements/loop circumference...before radiation is significantly compromised, when the match is secured at the antenna with the auto tuner?

Thanks in advance for your competent comments.
Henrik.

(I filed a similar question at the tuner makers forum, but it is not that populated it seems, so I hope it is OK to ask here too (www.sgcworld.com))

Gary,
I use UHF bulhead connectors to bring the signals into the house (actually garage). The bulkheads go through the rear garage wall. Cables with 259 connectors screw into the bulkheads from inside and from outside. There are 4 of these. Instead of putting a big washer on each bulkhead, I have about a 2 x 6 inch piece of aluminum sheet (with 4 holes drilled in it). One of the mounting screws for the aluminum sheet connects to a ground strap, on the outside. To keep it neat, I have a second, identical, aluminum plate on the inside.

The nice thing is I can unscrew all the coaxes from the outside, and be completely lightning proof. OK, if it is alrerady raining, I do it on the inside. I found the 2 inch bulkheads won't quite reach through the siding and plywood, so had to go up to the next size. You can buy bulkhead connectors from Cablexperts. The whole ouside of the bulkhead connector is threaded with the same pitch as a 259 connector. They give you 2 nuts that go on there for nounting.

I have one antenna at the other end of the house, where I drilled a hole from the outside into the basement, next to the telephone and cable wires. Wall is too thick to put a bulkhead there.

I have two windows in my shack. One has an air conditioning unit.
Under the AC unit are two slabs of wood, to keep the AC unit off of
the ledge, level and to provide some support. There is a small gap in
between the two pieces of wood. I have 5 lengths of RG-8 coax coming
in between the wood and under the AC unit, with a bunch of insulation
stuffed in the spaces to keep the heat/AC in the room. My other option
was to run the coax into my crawlspace under the house, and drill a
hole in the floor of the shack, much in the same way that the TV cable
comes in.

The J-pole is essentially the same thing as a Zepp antenna which was
trailed from the Zepp airships. Sounds like exactly what you need.
feed a 1/2WL monopole (wire) with 1/4WL of ladder-line and let it
hang down, just like the Zepp airships. One wire in the ladder-line
goes to the 1/2WL wire and the other wire goes nowhere.

Walter Maxwell, in "Reflections", says a dipole should be a minimum
of 3/8WL. This is, admittedly, an arbitrary length but is, IMO, a
good rule of thumb. Note that the G5RV is about 3/8WL on 80m. Any
shorter and the SWR becomes a problem since the feedpoint resistance
is decreasing while the feedpoint reactance is increasing.

Scott,

I'm in the process of building a dedicated
ham shack in the corner of an existing
enclosed garage. This will be insulated
for year round use. I had to tear out sheet rock from the garage corner walls
in order to insulate them and run
electrical wiring. My existing framing is
2 by 4s spaced 16" on center. My plan
is to use a rather large electrical junction
box that is also very deep. Most
electrical supply houses have them.
The largest I've seen at Home Depot,
Lowe's, etc. is about 10 by 10 by 4".
The electrical stores have many sizes
...much larger. My plan is to use a
large one and fasten it between the
existing studs close to the floor. I'll
use a hole saw in the back of the box
for multiple large size conduit fittings.
I will avoid using an "LB" type fitting
due to the tight bending radius (Not
good for coax) but instead will use
the prebent conduit 90 degree bends.
This will call for a larger hole on the house
exterior but some mortar and a well placed
landscape bush will take care of that.
I'll have the box grounded. I'll use
bulkhead type lightning/surge arrestors
and mount them to the box cover. Hope these ideas help.

73,
Mike

Striving for maximum gain for a given lot size is a good goal only if you have the option of rotating your antenna or you're interested only in communicating only in a small number of particular directions. It makes no sense to increase the gain of an antenna (which has to narrow its beamwidth) if the narrower beam limits the directions in which you can effectively communicate.

In your earlier post, you supposed that there won't be a "best" antenna, only opinions. Yes, that's true, but the reason there's not a "best" antenna is that "best" is different for different people and different applications.

Your posting makes it sound like bigger antennas are less efficient. On the contrary, it's difficult to make a small (in terms of wavelength) antenna that's efficient, and just about impossible to make a very small one that is. By contrast, most antennas on the order of a half wavelength or larger are very efficient without even trying. (The exception is when there's strong coupling to or current flowing in the ground, as with a ground mounted vertical.) The EH and "cross field" antennas are no exception -- they're very small antennas, and all objective and credible measurements and modeling results show them to be very inefficient.

"Scott Vanzandt" is
> ...looking at building a new home.
> ...conduit...
<snip>

My house (as opposed to where I am living right now) has pretty much every room equipped with the following arrangement...

A outlet box (or several) with a short length of conduit that runs down to the unfinished basement. For the second floor rooms, each rooms' conduit runs up to the loft and from there is a collective honking big conduit that runs down to the basement. The boxes are installed in the corner of each room (usually the best locations are obvious). Installation is trivial for the first floor rooms - a suitable outlet box and a length of conduit joined with the appropriate pressure-fit fitting (about $2 per room). Second floor rooms is just a bit more work.

The applicability of this arrangement to ham radio antenna coaxial cable (high power HF, length sensitive V/UHF) depends upon the layout of your house and your own plans. Outlet boxes are a bit small for the bend radius of anything larger than about RG-8X minifoam. One could rig up larger homemade "outlet" boxes of course - especially on an inside wall (or in the floor). These would be planned to end up under the operating desk.

On the other hand, this arrangement is perfect for all sorts of smaller cables (SWL antennas, satellite or cable TV, telephone, intercom, PC Network, temperature sensors, security cameras, etc.). I've been able to change my mind and swap TV and telephone locations very quickly. I feel happy that I could add a new cable without tearing the house up (saves time, saves effort). Most hams are interested in these sorts of gadgets as well...right ?

Yup...we built airplane fuselages out of it....had a piece used as a mast (wrong size for landing gear!!) on a 100' tower in NC which was up for 20+ years after my dad died (W4QAZ Dick Austin). Never had a problem, even went thru a few major storms w/o blinking. Tough stuff!

Why not make your dedicated garage shack available for remote control over a LAN? My station's in the basement, but I can control it from anywhere in the house over a wireless LAN from my notebook computer, and monitor all important aspects of operation. For audio within the house you can use Personal Radio band transceivers, or with less quality you can use NetMeeting over the LAN.

Several factors can contribute to a "loss of radiation". Their practical significance may be a matter of some debate. Some of these issues are system gain issues and some of them are antenna efficiency issues.

1) The tuner will introduce some loss into the system. For practical matters this may be negligible.

2) With increased SWR, the absolute power loss in the transmission line increases.

Part A. Assume the same forward power arrives at the antenna. With a matched antenna there is no reflected power. With a mismatched antenna, there is some level of reflected power. Some of this reflected power is dissipated in the transmission line. This increases the absolute power loss in the transmission line.

Part B. The SWR between the tuner and the antenna will be the same as without the tuner. The tuner essentially compensates for the mismatch loss introduced by the high SWR by increasing the total forward power arriving at the antenna. The relative level of power reflection at the antenna remains unchanged. With the tuner, the absolute forward and reflected power in the transmission line increase. Therefore, the absolute power dissipation in the transmission line increases.

3) The total power delivered to the antenna is a direct function of the antenna's resistance, which is comprised of two components - radiation resistance and loss resistance. As the antenna becomes smaller, the total resistance decreases. However, the radiation resistance decreases at a faster rate and the antenna efficiency decreases with smaller size.

The SGC will work fine with .25 wavelength at the lowest frequency...I believe it will match down to 8 ohms...but they have so many models, I don't remember which is which. There will be some loss...maybe a db or two depending on the Q of the coils in the SGC...certainly nothing that would prevent you from getting out solidly.

I have an SG-237, and have used it with .25 wavelength dipoles. The main thing to remember about these tuners is that they are inherently unbalanced...and for the auto circuitry to work right...the "cold" side needs to be well defined. SGC recommends lengthening the cold side about 5% to facilitate this. If this is not possible, then you'll need to provide a counterpoise to connect to the cold side.

Be careful about using a length that will be near 1 or 2 wavelengths on any band, since the voltage will be very high and hard to tune.

Homebrew Antenna Shootout
http://www.turnpoint.net/wireless/has.html

Could Fracky, et al., add their products to the line-up for a
ranking? It seems simpler than FOMs and GOs.

Results in a format like this would settle the question, would they
not?

The rule of thumb is still good. Let's turn it around. How much loss
are you willing to tolerate? half your power? 3/4 of your power?
The losses in the tuner at the antenna increase as the antenna is
shortened radically less than 3/8 WL. The 'Q' of the coils in the
SGC-230, for instance, is not all that high being wrapped on
iron-core toroids.

I don't think that would be a problem. I've seen the SGC-230 used on 75m
with a CB whip. Now there's a high voltage.

Source record: 132301

Jim,
This was the choices given, "A tapped coil at the base or just a fixed length vertical with an antenna tuner?". With that in mind, where would you think the 'best' place to match impedances would be, at the input of the antenna, or at the transmitter end of the feed line? Remember, this is a multi-band antenna. The feed line doesn't have to know when to change it's attenuation, or even have to change at all.
'Doc
PS - Besides, I have 'smart' coax.

I'm looking for commercial source(s) for a "Drive-On" Antenna Mounting Base Plate System(where you drive your vehicle onto the base plate to secure the antenna base from toppling). This is for mounting a fairly large Shakespeare Military wideband(30-512Mhz) Vertical Omni Antenna. Since it is for a military application, I'm looking for commercial solutions(not home-brewed). Anyone got any suggestions for sources?

Thanks, Stewart

Hi Jason,

I think the answer to both questions is "Absolutely". The black coax shield indicates the coax has been around for some time and may have accumulated water, so I'd get new coax. Take a look at RG-58 characteristics compared to RG-8. If you are running HF and no amp, you may find RG-58 very useable. Certainly a loose coax fitting would not help your reception or transmission.

Good luck and Good DX,

Bill, W4WNT

This is the closest to the real way to do the job.

Use a 1/8" thick aluminum panel to mount the polyphaser lightning arrestors.
Add a heavy ground lug to the panel to a SHORT THICK wire to your outside
ground rod.

> Jim
> N8EE

Hi Jim,As a retiree I am now a 'nothing' but we have the same
background except you are electrical where I was mechanical albiet at
G.E.and English to boot.
You make excellent points and I was speaking somewhat tongue in cheek,
but I do feel there should be a common 'best antenna' chart possibly
based on efficiency or what ever.But let us look at the latest "new "
idea, the IR antenna which appears in great demand because it can

pursue a constant 'high' gain across a
band, which if you compare to other multi frequency antennas is quite an achievement and realistic (higher merit), whereas other manufactures claim a 'point' gain without reference to drop off in gain at band edges ! But the fact is that one could increase gain even more, much more, by using the total physical length, what ever length one wishes to use, to radiate on 'All' frequencies by incorporating a collinear aproach or design, tho some would argue that a collinear aproach does NOT supply extra gain ! So I used that as a background to emphasize some way of getting an 'order of merit' so that efficient use of 'dormant' parts of an antenna, say in a triband element,aproach other than bottom edge of twenty metres would reflect a true merit index increase.
Now ofcourse it will not take off. Some will argue that traffic lights are blue if one says it was red but it can be a lot of fun if no malice was intended. One person explained in excellent detail the technical side of the question and another urged that we all use similar definitions before we decide to generate new ones, both of which are excellent points.Yes, there are undoubtedly some very knowledgable people in this group and when they are encouraged to partake in true debate instead of sarcasm then we all get to learn a bit more, this being the main reason that I am here. Yes I am not good at communicating but for me it is better than being silent.
By the way I like your reference to history since it reflects the amateurs antenna aproach to reach a point where all radiation is generated from a flashlight.This is a difficult task and many are derided for even pursuing the idea but then even Gallaleo was villified for presenting new ideas. Even the inventor of the typewriter was ignored for over twenty years before one finally got installed in an office. Obviously in both cases the opposition were skilled debaters lacking in knoweledge and intent in killing the messenger, some of which are still around today.
Have a great week Jim, I enjoyed the interchange.

>makes it unpalatable at the same time.

Yeesh. "Unpalatable" is putting it mildly. That's a very inventive
mixture!

>Tip: Wear latex gloves if you do this.

... and perhaps a respirator and mask as well. Dave's is high-test
capsicum oleoresin. You really don't want to be inhaling this mixture
or getting it in your eyes... it'd hurt like hell.

Unless your local rodents have been raised on a diet of bitter melon
and habaneros, I'd expect them to stay far away from this potion!

Robert,I have only experimented a little with verticals
but may I suggest a different direction to the norm for you to review.
Since radials are a necessity for 'efficient' verticals why not think
of using a vertical dipole form ? This puts the feed point away from
the ground and where the coax feed can be "shielded" by routing it
thru the center of the vertical arrangement and then routed
underground. I have heard that such arrangements provide a lower angle
of radiation than the standard vertical which makes it useful for DX.
It also would meet your needs as far as neighbors are concerned. I am
sure that others could add to this aproach in such a way that we all
could learn more.Just a thought.

==========

Nelson, I've thought a little more about it.

You have a receiver with a 50-ohm input impedance. It is preceded by a length of coax cable. But the input impedance of the cable is still 50 0hms. So the 600 ohms down to 75 ohms problem (if it is a problem) is exactly the same whether the coax is inserted between antenna wire and receiver or not. There is just a small fraction of a dB extra signal loss in the coax. The loss in the un-un is the same whether the coax is there or not.

It is true that the characteristic impedance Zo of a high, long length of 14-gauge wire is crudely 600 ohms. But because the the far end of the wire is unterminated the angle of the 600-ohms input impedance will vary with frequency between 0 and 360 degrees and the resistive component of input impedance will vary between about 40 and 2500 ohms with a mean of about 350 ohms.

So the mismatch loss at a particular frequency without an un-un is anybody's guess. An un-un will reduce the MEAN mismatch loss by crudely 4-5 dB. At some unkown frequencies, where antenna impedance is already less than 75 ohms, it will actually increase loss. But this is hardly relevant since what matters is signal-to-noise ratio and an un-un can have no effect on this all-important feature.

Suggestion - borrow an un-un and see what practical difference it makes (in or out) over the whole MF and HF bands.

Isn't ten turns of coax on a ferrite toroid a unun if it connects
coax to coax and a balun if it connects coax to ladder-line?

I think an un-un is an unbalanced-to-unbalanced wide-band auto transformer
of unspecified ratio with one end of the winding grounded.

By making the right connections an ordinary 4-to-1 impedance-ratio balun
becomes a 4-to-1 un-un.

But I don't want to make a Federal case out of it. I'd never heard of the
thing before yesterday.

Source record: 132220

Reg, Cam, Art et al,
Yeah, that's what I'm talking about... thought the term was in more
common use, but perhaps I fell
into the trap of one or two purists who insisted on differentiating.
The scenario here, is that I was putting up a random wire at some little
distance from the house wiring
and consequent noise, and using coax to feed it to the receiver. The coax
is 72 or 75 ohm impedance,
I forget which, because I had it on hand. The receiver (SP600) input is 100
ohms impedance. So...
unbalanced to unbalanced.
And Reg, maybe you can correct me on this. My understanding is that by
using the coax with grounded
shielding to feed to the receiver, I can reduce local noise pickup. Also
that an unun (or reconnected
balun), can match the impedances, at least somewhat, and smooth out the
nulls-peaks of the antenna
over a broader bandwidth. The original question was simply whether a small
ferrite toroid core out of
dead computer power supply would be suitable as a core for homebrewing the
unun/balun.
Nelson

Source record: 132221

From a previous post, 5 days ago:

This is a great antenna for a newbie to build and to model using NEC.
I did that 2weeks ago to get some antenna up for this weekends CQ WW
DX SSB contest. Here are the construction details.
2 6' 3/4" 0.125 thickness Al tubes
2 6' 5/8" 0.125 thickness Al tubes
15' Fiberglass Wind surfing pole
2 2" Stainless Steel Hose clamps
3 3" Stainless Steel Hose clamps
2 5" Stainless Steel Hose clamps.
2 1"x5" Strips of 1/8" thickness Al
1' 1" Sched 40 PVC pipe
8 2" #8 Stainless Steel Machine Screws + washers + nuts
4 2" #8 brass Machine Screws + washers + nuts
Silicone Caulking
450 ohm Ladder line
Tuner

Building procedure:
The holes you will be drilling should be big enough for #8 Machine
screw.
1. Take the 5/8" Tubes and Drill Holes at 36" and 39" from one of the
ends.
Sand the areas around the 36" Hole.

2. Take the 3/4" Tubes and Drill Holes at 2" and 5" from one and a
0.5" from the other end. Sand areas around the 2" and 0.5" sets of
holes.

3. Take the PVC pipe and Drill holes at 5" and 7" from one end. Widen
the hole on one of the sides of the PVC pipe so that the head of the
brass screw will completely go through the hole. Make sure you do not
widen the hole on the other side.

4. Take the 2 metal strips and drill 2 holes 4.25" inches apart along
the centerline of the strip.

5. Take a hacksaw and cut a few 1.4" slits on both ends of the PVC
pipe.

Assembly.
1. Take the 3/4" tube and push the end with the hole at the 0.5" into
the PVC tube. When the hole shows up on the first 5" hole put a brass
screw through the side with the big hole. The head of your brass screw
will be directly contacting the Al tubing. Put a washer and a nut and

tighten it down. Repeat the proceedure for the other side. Now Slide the 2 2" hose clamps over the PVC pipes. Align the clamp to one end over the slits and tighten using a nut driver. The PCV will compress and grip the AL tubing. Repeate proceedure with the other clamp.

2 Now take the 5/8" Al tubing. Line up the hole at 36" with the hole at 2" on the 3/4" tube and put a brass screw though. Tighten. Put stainless steel screws through the hole at 5" on the 3/4" tube and the hole at 39" on the 5/8". Put the metal strip in and tighten. You should have a T which not going to wiggle or droop. Repeat process at the other end.

3. Take the ladder line and hook the 2 ends to the Brass screws in the PVC pipe.

4. Apply caulk liberaly at all the points that have brass screws.

5. Overlap 3' of the bottom end of the antenna with the Fiberglass pole. Spread out the 3 3" hose clamps in the 3' overlap zone and tighten.

6. You are almost there. Lift the whole asembly and tie the fiberglass pole to a vertical support using the 5" hose clamps.

7. Run into the shack and tune it to the band of interest. 20 15 and 10 work real well.

The first contact for me with this antenna was RZ4FA on 14.225 and he gives me a 5/6 Followed by AA3b on 21.387. The next day was LW9DHR on 28.344. NEC tells me that the radiation resistance on 20 is about 15 ohms, on 15Mtrs it is about 35, on 10 it is about 60.

I used the Al from a Full size 20M beam I used to have. The Fiberglass pole was picked up for free during the Dumpster Day in our community. Hose clamps and screws etc were from Home Depot.

Build and have fun. See you on the Air.
Regards
Nat Gurumoorthy AB6SJ

hi

i've got a question about shunt feeding a us towers tx455
crank up tower. the tower is a 3 section, telescoping tower.
each section is hooked to the next section with 1/4 inch
steel cable and secured with large galvanized bolts at each
end. my question is, does the bolted steel cable from one
section to the next, consistute a good electrical/rf connection?
my initial thoughts say no, it is not a good connection, and
trying to use the tower as a shunt feed 160m vertical will
probably generate swr that varies as well as rfi problems
as well. anyone got comments, thoughts they would like
to share, either pro or con?

Oops, if you look at the previous post, it is not built like a force 12.

How about someone out there tell us how to make a sigma 80, 40 or 20 ?.

What would analysis say about these sigma antennas ? I mean, about using long T-bars at the end of their dipoles, what does it say for efficiency, radiation angle, etc ?

I think the sigma 20 is roughly 16 feet overall with 13 feet T-bars at the ends?
the sigma 40 is roughly 24 feet overall with 10.5 feet T-bars ?
the sigma 80 is roughly 36 feet overall with 14 feet T-bars ?

Maybe 450 ohms line and tuners would tune these on other bands ...

Howdy,

If you have a basement you can have the rf ground installed through the basement floor or, for that matter, through a basement wall.

Provide means to run lots of wires from the outside of the house to the inside, including means to remove and pull in new or additional wires.

One ham buddy of mine has made provisions to disconnect ALL such wires at the outside of his house before they ever get in. He has been hit by lightning twice and is kind of gunshy.

It may be a good idea to bury plastic pipe under driveways or other paved areas by the house in case you want to run underground wires. (I wish I had done that when I had a new drieway poured many years ago.)

Roy Lewallen <w7el@eznec.com> wrote in message news:<uru33gl3trh699@corp.supernews.com>...

> Your posting makes it sound like bigger antennas are less efficient.

Well I intended to say "amateurs are gyrating towards bigger is
better"
and there is nothing wrong with that if you have money.

On the contrary, it's difficult to make a small (in terms of
wavelength)
> antenna that's efficient,

NOT if you look at it from a gain per unit length aproach which most
seem to dislike. As you well know a capacity hat can make a difference
in length with only minimul effect to gain, very important to those
who do not have money.

and just about impossible to make a very small
> one that is.

'Just about but not quite' is subject to change as the state
of the art improves is it not?

> By contrast, most antennas on the order of a half
> wavelength or larger are very efficient without even trying.

Stands to reason they would be larger in gain unless they are
also encumbered with inert non radiating elements. To have extra
elements on a multi bander array to only accomodate a single band
gyrates towards a negative in my mind

> The exception is when there's strong coupling to or current flowing in the
> ground, as with a ground mounted vertical.) The EH and "cross field"
> antennas are no exception -- they're very small antennas, and all
> objective and credible measurements and modeling results show them to be
> very inefficient.

>Very true. But difficulty has not stopped the quest for smaller
antennas to achieve Zukof's statement about 'point radiation' in a
similar fashion to a flashlight (torch in the U.K.) and such a quest
will produce many failures on the way tho each failure also
constitutes a small advance.
If I remember correctly ,you yourself worked hard and long on a
verticle phasing problem and eventually met with success, but only
after unsuccessful attempts. It didn't stop you in your quest and you
finally won so we can hardly ridicule those who are experiecing
failure at the present time.

But for all the above I am heartened by your comment "it is difficult
to make a small...." which I totally agree with and I am encouraged
that you didn't say "impossible" which puts me on the same wavelength
as yourself.

Personaly I believe that my antenna work (I know ,it agravates many
of the members every year of this news group who deny my claim) is a
move forward in the state of the art. Like the typewriter it may take
twenty years before it is built upon, but I will not walk away from
what I do because many see it as a total failure and a 'waste' of
peoples time, the reason being is that I enjoy this type of
experimenting and sharing.

(Naysayers, I am in no way saying that I am an equal to Roy in
antennas and hopefully he is not 'wasting' his time with his 'sharing'
efforts with this newsgroup)

Best regards
Art

What you are refering to, Doc, is extra loss due to SWR mismatch,
which is in addition to the loss in the feedline.

I have done it both ways---match at the antenna or match at the rig
end of the coax. They both work.

But if you put the matching network at the feedpoint you will have to
1) run outside at 2am in the snow to change bands, 2) use a broadband
matching network (not easy to come by!), or 3) have a remote
switching/tuning system.

I think it is a matter of personal preference. Most recently I have
connected the coax directly to the bottom of my 35 foot vertical, and
use a matchbox at the rig. Seems to work fine, 160 to 40 meters.

Remember, most hams put too much emphasis on SWR anyway.

Nelson Gietz wrote:
"The receiver (SP600) input is 100 ohms impedance. So....unbalanced to unbalanced."

Like Reg, I doubt any significant benefit from an impedance transformer between the antenna and receiver.

I used a SP-600 with a Beverage antenna in Europe to listen to US medium wave broadcasts for yearts after midnight when the locals signed off. This was on one of the world`s largest shortwave broadcast plant sites, we thought it was the biggest at the time, and we weren`t signed off! We also used SP-600`s with our Wayne Kerr admittance bridge for antenna adjustments while all the 100KW transmitters were shaking the aether all around us. We also had 51-J`s which proved worthless on the site due to overload and birdies.

Alas, I don`t have a SP-600 now, only a much more modest HQ-170 ham band only receiver. Its manual says:
"The HQ-170 is designed to operate with either single wire antenna or a balanced transmission line type."

It`s been about 45 years since I was operating SP-600`s but surely they are similarly equipped for either balanced or unbalanced antenna input. So, Nelson should be well equipped without any isolation signal transformer at the receiver.

Hammarlund also says of the HQ-170:
"The single wire or balanced antenna for the remaining bands (other than 6-meters) is connected as shown in Figure 2 or 3.
The front panel antenna trimmer control (Figure-5) permits a good impedance match to most antenna systems of 50 to 600 ohms (on all bands).
For general coverage, single wire antenna of 20 to 50 feet length will provide surprisingly good reception. (We nearly always used rhombics.) A long single wire outdoor antenna, such as the one shown in Figure 2, will generally provide entirely satisfactory performance. This wire may be 50 to 150 feet long.

For best reception, the antenna should be isolated as much as possible from neighboring objects and at right angles to power lines or busy highways so as to minimize interference pickups.

Optimum performance on a particular amateur band or other narrow tuning range will be obtained by using a tuned half-wave dipole or folded dipole using 300 ohm transmission line or other suitable lead-in, as shown in Figure 3.

To tune the one-half wave length dipole use the following formula to determine the length of the antenna:
Length (feet) = 468 / Freq. (MHz)

Each arm (1/4 wave length) is half the length obtained from the above formuls.

A good ground, although not always necessary, will generally aid reception and reduce stray line hum.

Best regards, Richard Harrison, KB5WZI

U.S.Towers said the answer is "no", there is not sufficient connectivity in the crankup tower. However, it appears that the tower manufacturers' answers to almost any question is "no" due to potential legal exposures.

I asked the question on the Towertalk server, and a number of people replied that they are using their crankup towers (including the TX455) as verticals without problems. A few said that they ran a separate wire from the top to the bottom. Most did not. No one said that they had tried it and it failed. YMMV.

I plan to try it (using a half-sloper instead of shunt feeding) when I get my TX-455 in place. (I am currently wondering how much over specification there is in the concrete requirements for the base. I have 150% of the amount of concrete they specify, but mine is not as deep as they specify.)

Hi Stephan,

You can do this yourself with the free version of EZNEC (become one of that army of experts that populate the wide world web).

For the rest:
the Sigma 20 looks its best at 25ï¿½ with an astounding -0.08dBi....
drivepoint Z = 69.45 + J 192.2 ohms
(if we flung it high, into outerspace, Z = 43 + J 182 ohms)

Analysis reveals that the antenna structure is naturally resonant at a much lower frequency of 11.6MHz. So, as the SWR of the naked structure does not compare to the advertising literature claims, some mild speculation (in their ad's favor) would tend toward there being a passive component added to shift the frequency. This speculation is supported by their claim of a direct 50 Ohm feed.

Again, using EZNEC, I added a -200 Ohm load near the source feed (a cap in series) and the resonance dropped dead on to 20M. Further, the SWR shows a BW of 13.4MHz..14.7MHz - and conforms to their ad:
>The operating bandwidth is <1.5:1 across the whole 20 meter band.

This being a short near ground antenna sparked a moment of reflection with a derivative design, an "optimal" one from the fractal kitchen:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
which, when you scroll down to the simple alternative, you will find to be the Sigma style doing quite well (even if not optimal :-)

Art Unwin, KB9MZ wrote:
"---the Yagi provided a solution for that (long-wire destructive interference in the desired direction) which started down the road to an ideal situation by reducing element lengths down to a single point as with a flash light or lazer.'

Antenna loading coils started down the road to a single point source antenna. Gain is produced with equal, if not better, control by using all driven-elements instead of parasitic elements. This predates the parasitic-element Yagi. The Yagi advantage is the convenience of a single feedpoint.

No mystery exists. An elemental (very small) dipole can radiate unlimited energy given unlimited current. Problem is system efficiency in making energy flow into a very small antenna. The flash light and laser aren`t really small in terms of wavelength. The flash light reflector is bigger than most microwave reflectors I`ve heard of in terms of wavelength.

Fame and fortune might come to the inventor of a tiny antenna system with a large radiation resistance and a small total loss resistance.

Hi All,

Odd how thoughts borne of one idea careen into other threads. In
reflecting on the simple side-by-side comparison made between the
Sigma style and fractal style antennas, a revelation came in terms of
Cost and FOM.

Which of these two (if the book-cooks could jimmy this in their favor,
they would) has proven to be more successful in the real world?

1.) The fractal with an 0.0138 FOM advantage - and never built after
its inception much less produced for sale to the 20M community?

Or

2.) The Sigma with the Cost advantage selling quite well for years,
thank you, to that same 20M community?

> like a little explanation if possible?

You don't say where the tuner would be mounted.. A tapped coil would probably be less loss than using an autotuner at the base of the antenna. The reason I say this is because the tapped coil would likely be a larger and more efficient inductor than the likely smaller one in an autotuner. But the autotuner would be much easier to change bands. If you use a tapped coil, you really don't need a tuner. You may well need a bit of impedance matching though. Think of the antenna as a tall "bugcatcher". Using a tuner at the shack, feeding coax, and then a vertical with no coil, would be the worst way to go. Quite a bit of loss on certain bands due to the high SWR on the coax. You should match at the antenna.
>
> What band should the radials be set for? If full size radials are not
> possible should they just be made as long as possible?

If a ground mount, the most loss is at the base. So thats where you want the bulk of the wire. Many short radials are better than just a few long ones for a certain amount of wire. Of course, the more of them, and the longer, the better.
>

> dipole, but the neighbors wouldn't mind seeing a single vertical
> sticking up above the house 20-30'.

If this antenna is elevated, the radials must be resonant for each band used. That means for each band used, you need at least one or more 1/4 wave radial. On certain bands, a lower band 1/4 wave radial can be used as a 3/4 wave radial on a higher band if it works out that way. IE: a 40 m 1/4 wave radial will function on 15m as a 3/4 wave radial. 1/2 wave radials will not work. Random length radials on an elevated antenna will not work well either. They must be resonant and show a low impedance to function. If you plan on 80-10 use, it may well be easier to use a ground mount. That way radial length doesn't

matter, and you can get to a tapped coil to change bands on the antenna. Also , you have access to any matching device used, if you would need to adjust it. MK

Hello,

I am planning to make a Loop antenne to use on mediumwave and perhaps on shortwave, now i would like to now the following:

1) is there a formula to calculate the wire lenght ?

2) is there a formula to calculate the frame size ?

Perhaps its seem stuppid, but i find a few pictures of this loops, but there are no calculation on FREQUENCY versus WIRELENGHT

So if you can give me the answer or someone nows that can help me, i will be thankfull.

Greetings and gd dx-ing

A common value to use is 1005/F where the result is in feet. For
instance, a loop for 10.05 MHz would be 100 ft around.

You'll find everything you need here. If you have Excel there is an
excellent calculator link.
http://www.mindspring.com/~brucec/amloop.htm
I don't think you'll find much on SW loops because they generally are
not very effective.

Hi Richard,

I doubt the fame and fortune part. To a great extent, the small antenna issue has been solved however.

Less than 0.06 WL tall, self-resonant, 55 ohm radiation resistance, efficiency greater than 95%, Q within 1.5X fundamental limit, operates in a vertically polarized monopole/dipole mode.

Art Unwin KB9MZ wrote:

> Think about it, we think of gain as an order of merit
> so the tribander with double the element length of a 1/2 wave
> dipole has the SAME 'order of merit".

Your equation seems to be merit = gain/length.
Use upper case for the dipole and lower case for the
tribander. You specified M = m and L = l/2.
Substituting: G/L = g/l; G/L = g/2L; therefore G = g/2

If that is true, then the gain for each band in the
tribander must be 2/3 the gain of the dipole.

Real world, the gain on each of those bands is ballpark
4 Dbd greater than a dipole if you are talking about a
yagi. You seem to be, as you mentioned turning radius.
If you are talking about a trapped dipole, then the
length is approximately the same.

So the conclusion is:
1) merit cannot equal gain/length
or
2) if merit does equal gain/length, then
the merit for a dipole cannot equal the merit for
a tribander twice as long.
or
3) I have not understood what you said.

And I am really lost on where you get the length.
Dipole length is clear, but how do you arrive
at the length for the tribander? If it is a
yagi and you are talking total element length,
wouldn't the tribander length be roughly 3 times
the dipole length? Does turning radius fit in
to the length computation somehow?

OK. I am an ignoramus. There must be a rub. The conductor must be cooled near absolute zero? The antenna wave propagation must be slowed by a special unobtainium dielectric material to shrink antenna size? Or, what`s the trick?

I think I qualified my statement, saying something about TOTAL system efficiency just to try to avoid mis-statement on a technicality.

If you could also make it frequency agile from 2MHz to (X)X GHz (upper limit seems to vary), then there are some "MIB" that might be interested. I trust that they're not asking for too much... ;-)

> I doubt the fame and fortune part.

Oh, cost is no object.

No trick at all. It's a real antenna. Designed, modeled, built and tested.
Electrically small (h < 0.06 WL), radiation resistance matched to 50 ohms,
high efficiency (low loss resistance), low Q, vertically polarized monopole
pattern.

i use a dx399 shortwave radio in a dumptruck. my antenna is six feet of wire strung from the mirror down to the dog on the hood. (the bulldog looks like it is straining at a leash) daytime shortwave reception is surprisingly good but medium wave is terrible. (the antenna jack uncouples the ferrite antenna) as i was driving today i wondered if a coiled length of wire at the end would help, if for no other reason then by getting more wire into the air. is there any benefit to a wide band antenna to be loaded in some manner? (those fiberglass cb antennas for trucks seem to be like that, all coiled at the end) or would this narrow the frequencies received? is there a formula that tells how much wire i can coil before it starts to choke out the frequencies of interest? would this small amount of added wire add enough signal to bother with? and how can i get enough wire out the window of a dumptruck to receive medium wave?

It operates in a fundamental series resonance and operates in a
monopole/dipole mode. There is no top lodaing. It is however more of a
loop configuration than a monopole. The wire diameter is about 2.6 mm and
is made of copper.

Larry,

Your best bet would be to use some finger stock, stainless steel strapping, or something that allows a movable, electrically conductive connection at each tower section.

why not a tube of steel (slightly larger) welded to a 10" plate, holes to mount
to spare tire,(3 or 4 lugs is enough) tube is to be 1 foot per 10 feet of mast. Dont forget to properly ground the antenna per ground wire, ect.. Lay out mast on ground, attach ant, mount plate, lean it to insert mast, lay it upright, waa laa.
I dont like the idea of having to drive on to a plate..has anyone been injured when you drive off? does using your idea
require two or more individuals? How high is the mast?

Jim,

Hydrogen is used all the time in Europe and the balloon I crew for was built in Germany and is dual rated for both hydrogen and helium. It has only been the last few years that hydrogen has been used here in the US. It is somewhat safer to use helium, but it is perhaps 4-6 times as expensive. The high expense has hindered growth of the gas balloon pilot population in the US.

Sorry to get off topic.

Vic

ehsjr,
You haven't discovered the trick of reading Art's
post yet. First you have to decode what he means
when he says 'tribander'. An 'Art' tribander isn't
a three band yagi like you might suspect. In this
case, it happens to be a three band rotatable dipole.
And he seems to think that removing the traps and
using the 'full length' of the dipole on all three
bands should be not only possible, but 'better'.
The 'decoding' process isn't too difficult, it
just takes time (or in my case, someone told me),
but is essential for understanding...

I use a 33 ft rotatable dipole for 20m, 17m, 15m, 12m, & 10m.
It is an even better antenna on 10m than it is on 20m. I feed
it with a variable length 300 ohm ladder-line and it requires
no antenna tuner.

"Don`t sweat the small stuff."

Thank you for the advice. My unfamiliarity with optical wavelengths is obvious.

I`ve sometimes wished Johnson & Smith or someone sold fantastic eye glasses which converted r-f to the visible spectrum for easy exhibition of radiation patterns. J&S used to advertise "X-ray glasses" but I suspected they operated via the user`s imagination. Film and other media can be sensitive to radiation outside the limited spectrum humans are sensitive to, but all the r-f patterns I`ve seen were plots.

Best regards, Richard Harrison, KB5WZI

Seems to me that in principle, it _might_ be possible to do a dualbander (10/20) somewhat along the lines of what Art is proposing. Rather than a simple set of traps, you'd install some sort of phasing section in the middle... maybe a bent-around transmission-line loop like the Maritime Super J-Pole uses. This would, in principle, allow the two halves of each element to act in a collinear fashion and give a bit of directional gain.

I think you'd still need to install a set of traps (or a relay) inside the loop of each phasing section, to "short it out" for operation on 20 meters. Otherwise, you'd end up with a really funky 20... quarterwave radiator on the inside, a quarterwave non-radiating phasing loop, and then another quarterwave radiator on the outside which would be entirely out of phase with the inner quarterwave. I don't imagine that the combination would radiate terribly well ;-)

I'm not sure how you could shoehorn a 15-meter antenna into this arrangment... use a standard 15M trap outside the phasing section, I guess. I can't see any way to fit a two-segment 15-meter collinear into a 20 and make it work.

I'm not convinced that this approach is at all worth doing, though. Yes, it could give a few dBd of gain on 10 meters, compared to a standard triband trap dipole having the same element length. However, the added phasing sections would be quite a lot heavier than a standard trap and would add significantly to the antenna's wind cross-section. They'd add weight, hassle, and might require the use of thicker elements to hold up the weight (which would be halfway out the element, adding quite a bit of lever arm).

I'd probably just go with a triband short-boom two-element trap Yagi, since that would give (I suspect) equal or better forward gain on 10 (and quite a bit better on 15 and 20), and a useful front-to-back ratio (which a phased collinear dipole would lack), with only a very modest increase in turning radius compared to the original trap dipole.

> My understanding is that by
> using the coax with grounded
> shielding to feed to the receiver,
> I can reduce local noise pickup.
==========
There's only one thing I'm sure of - it won't make it worse!

If depends on noise characteristics and what sort of parasitic antennas it radiates from. It's all near-field stuff. In the domestic situation with wires galore, unless the receiving antenna runs alongside a power or lighting cable for an appreciable distance, screening the antenna wire might not make much difference. If it's noise spikes as from on/off switches and thermostats in the neighborhood much of the rubbish will be picked up by the unprotected parts of the antenna anyway.

If the noise sources are very local fluorescent lights, TV receivers, computers, switcher power supply harmonics, etc., and the coax is long enough to remove the whole of the antenna right into the back yard, then there should be an improvement. I have often been in that sort of situation myself but I confess I have never done any A-B tests. And I have never kept any antenna long enough to make an indoors permanent installation of it.

Perhaps grounding BOTH ends of the coax would be beneficial. It would certainly change the circuit configuration and the sort of coupling which takes place.

The usual connection to 'ground' from the receiver itself is an integral part of the receiving system. It is surrounded by noise radiators and ends by being connected to a noise generator - the incoming domestic power supply. To ask a rhetorical question - should the receiver power lead be replaced with twin-ax ?

I have found a choke wound on a ferrite rod inserted in the 50Hz mains lead to be beneficial. At least it makes one feel more relaxed until the XYL's vaccuum cleaner is switched on!

(PS. Switcher power supply ferrites should NOT be used for HF wideband transformers. And un-un's do not smooth out the peaks and troughs in antenna impedances. The peak/trough ratio remains unchanged. But the MEAN mismatch loss between a 600-ohm antenna wire and a 50-ohm receiver, over the MF and HF bands, is reduced by a few dB.)

Why is this? Low frequency ferrites (e.g. Fair-Rite 70 series or type 43) are commonly used for HF wideband transformers, except for very high power levels where heating might be a problem. The two switching supplies I've designed for production have used ferrites which would be very suitable for HF wideband transformers. What ferrite characteristics are you thinking of that would make some unsuitable?
